— THE CITY OF LONDON DAY CENSUS. — The ordinary census is based on the enumeration of all those persons who slept or passed the night at a given date in a particular locality. It is evident, even in the case of the metropolis generally, that as so many persons now sleep in the suburbs, the result must be very fallacious, and this remark applies with special force to that comparatively small district the City proper. Small though it be no one will deny its vast importance from a commercial point of view. The City authorities then did wisely to organise a day census, and this they did by ascertaining the number of persons actually resident within the City boundaries, and the number of persons entering the City during the day on foot, by rail, or other conveyance. The report before us gives a very interesting summary of results, to some of which we may here allude. The number of persons residing in or employed in the City during the day was 261,061, of whom 105,577 were adult males; 44,179 were females, and 21,305 children under fifteen. The total number of persons who entered the City by one or other of the entrances amounted to 707,563. Of these, 589,468 entered between 5 A.M. and 5 P.M., 739,640 during the sixteen hours between 5 A.M. and 9 P.M. inclusive, and 57,923 between 9 P.M. and 5 A.M. The number of vehicles of all kinds (except railway trains), was 71,893, thus distributed:—53,312 between 5 A.M. and 5 P.M., 66,900 between 5 A.M. and 9 P.M., and 4984 between 9 P.M. and 5 A.M. Of the total vehicles 15,066 were cabs, 6176 omnibuses. It will be remembered in endeavouring to estimate the amount of the traffic that these figures represent the passage of persons and vehicles into the City only. The exits may be estimated at about an equal amount. The total number of persons who were in the City during the night of April 3–4, 1881, was 59,526, a reduction to the amount of 32.5 per cent, as compared with 1871. On the other hand, the results of the day census in 1881, as compared with that of 1866, shows an increase of 54.4 per cent. The increase of persons entering the City since 1860 has been at the rate of 90,912 daily. The daily traffic in one direction only over London Bridge is estimated at 78,914 passengers and 10,733 vehicles. The City stands first in rateable value and assessment for Income Tax of all the towns in England. More than 4000 houses occupied during the day are entirely unoccupied at night, being left entirely to police supervision. As an illustration of the fallacies that arise from considering the night population only as the general census does it may be mentioned that one building alone occupies 1 acre of ground, rated at £5000 per annum, and let out in 135 different tenancies, and occupied by 252 employers and 275 employes, making in all 527 persons: represented in the Imperial Night Census by only four people! The amount of Income Tax under Schedule D. (Commercial) is £39,263,424—a far larger sum than in any other district of the metropolis, and more than seventeen of the most populous towns in England put together. An analysis is given of the various trades and employments followed by the residents and frequenters within the City boundaries. Nurserymen do not make a very large show, as, indeed, might have been expected—the numbers under this head, including "Nurserymen and florists, horticultural sundriemmen, and gardeners," being only thirteen. Under the head of Fruit and Vegetables are included—"Fruit brokers, fruit salesmen, fruiterers, fruit merchants, fruit dealers (dried) [the fruit, we presume, not the dealers]; vegetable salesmen, Potato salesmen, greengrocers, Watercress salesmen, hay and straw salesmen"—the total amounting to 343.

— "AGRICULTURAL STUDENTS' GAZETTE." — The last number of this periodical, edited by students of the Royal Agricultural College, Cirencester, contains a report of Miss ELEANOR ORMEROD's lecture on insects injurious to farmers, and on the mysteries of parasitic life, by Professor BROWN, in which, in addition to the older and better known parasites, the

Bacteria and the wonderful history associated with them are treated of.

— **BAILLON'S "HISTOIRE DES PLANTES."**—The part containing the *Compositæ* has just been issued, which it will be instructive to compare with the recent recension of Mr. BENTHAM in the *Genera Plantarum*. At a glance we perceive that the number of genera, which Mr. BENTHAM estimates at 800, is put down by M. BAILLON at 403. Dahlia is referred to *Bidenes*. The woodcuts are of their usual excellence.

— **THE "FLORIST AND POMOLOGIST."**—The contents of the February number are varied and interesting. In addition to the articles descriptive of certain varieties of Dahlia and of Plums, to be alluded to under the head of Plant Portraits, there are articles on Vine and Vine culture, double Scabions, Auriculas. The register of novelties is likely to become a most useful feature.

— **BRITISH MOSS FLORA.**—We have the satisfaction of announcing that the fifth part of Dr. BRAITHWAITE'S illustrated *History of British Mosses* is now published. Both plates and text evince the care and fidelity of the author.

— **MESSES. HURST & SON.**—In reference to the future management of this business, to which allusion was made in the obituary notice of the late Mr. WILLIAM HURST, we are requested to state that at the time Mr. SHEEWOOD was taken into partnership Mr. JOHNSON was also assigned an interest in the business, which will be continued as before, the business having been conducted by them conjointly during the illness of Mr. HURST.

— **PROLIFEROUS HYACINTHS.**—Mr. FRANK SOUTHAM, gr. to J. C. HAITER, Esq., The Cedars, Leamington, informs us that he has a bulb of *Norma*, in a 48-pot, which is now bearing fifteen spikes of flowers, with an average of 10—14 good pips on each spike.

— **LINNEAN SOCIETY.**—At the meeting to be held on Thursday, March 2, the papers to be read are—1. "On the Habits of the Coral-reef Annelid (*Palafo viridis*)," by the Rev. THOS. POWELL. 2. "The Lichens of New South Wales;" by CHAS. KNIGHT. 3. "Butterflies collected by Lord WALSHINGHAM in California;" by A. G. BUTLER.

— **THE WEATHER.**—General remarks on the temperature, rainfall, and duration of bright-sunshine, for agricultural and sanitary purposes, during the week ending February 20, issued by the Meteorological Office, London:—"The weather, though clearer than of late, has been generally cloudy, with occasional showers of rain. Temperature has again been above the mean in all districts, the excess varying from 2° on our south-western coasts to 4° on our north-eastern coasts. The highest reading recorded (57°) was registered in London and at Strathfield Turgiss on the 14th; while the minima, which occurred generally on the 16th, ranged from 27° in "Scotland, E." to 33° in "England, N.W." The rainfall has been a little more than the mean over eastern and central England, and equal to, or slightly less than the mean value elsewhere. Bright sunshine shows a considerable increase everywhere, the percentages ranging from 22 in "England, N.W.," and 23 in "England, S.," to 39 in "England, N.E.," and 51 in "Scotland, E." Depressions observed:—Pressure during this period, though high and comparatively steady in the south, has been subject to great and rapid changes in the north. Several depressions, some of which were very deep, have passed in an easterly direction over our northern coasts and across the North Sea, causing the wind to increase to a fresh or very strong gale from west or north-west in all the more northerly parts of our islands. At the close of the period, however, the weather was less disturbed, a large anti-cyclone being shown in the south-west, with moderate or light westerly breezes in nearly all parts of the kingdom.

— **GARDENING APPOINTMENTS.**—Mr. W. J. GILKS, late Foreman to Mr. DOUGLAS of Longford Hall, has been engaged as Gardener to A. HOWLAND, Esq., Higham Hill, Walthamstow.—Mr. JOSEPH THOMAS MULLIS, late Gardener to H. WILLES, Esq., Pittinaston, Worcester, has been engaged as Head Gardener to his Grace the Duke of DEVONSHIRE, Lismore Castle, Ireland.

MILTON PARK,

ONE of the seats of Earl Fitzwilliam, 3 miles from Peterborough, in a park of over 1300 acres in extent and containing some remarkable specimen trees the history of which is almost as far-reaching as that of the noble family to which they belong.

At the east side of the park there is a huge Oak, 26 feet in circumference, in which the late Earl, who was a great lover of trees, took a deep interest. From the north front there is a grand view through an avenue of Oaks leading to the church, and a fine view of Thistlemore Wood. The north front of the house is in the Tudor style of architecture and the south front Italian, and good views of the surrounding country are obtained from all sides of the building. The River Nene, which parts Northamptonshire from Huntingdonshire, flows through the grounds, and is spanned by an ornamental bridge, from which a fine tract of country is in view, and many pleasant local sights, including the charming Allwath Linn, situated at a high elevation with the Nene running parallel with its base. The Linn, as it is locally called, is in the form of an avenue about 1½ mile long with a wood on the left and a steep bank on the right running down to the water's edge. On this bank there are some fine Cedars, Oaks, Beeches, Views, &c., with openings which give some fine views of the country looking across the Nene valley.

The principal carriage drive is over a mile long through the sheep park and deer park, both of which afford much variety of scene and magnificent rural sights. There are several giant Elms in another portion of the grounds which are nearly eaten through by decay, but which are still preserved with the utmost care, and singularly enough, notwithstanding their decrepit appearance, there are still some of the limbs apparently possessing full life and vigour. The great interest which attaches to these trees is not so much because of their great age as because of their history. It was under their branches Sir William Fitzwilliam entertained Cardinal Wolsey, who had offended Henry VIII., and who had taken flight from the offended presence of his Majesty. Sir William, fearing to give offence to the king, and being in some way indebted to the Cardinal, selected the shelter of the Elm trees to hold a banquet, in order that it might not be said he had entertained the Cardinal in his own house. The trees, which form an ancient-looking group, are called the "Cardinal Wolsey trees," and are certainly more curious to look at than they are pretty in appearance. Traversing the pleasure-grounds from the mansion in a westerly direction there is a broad Yew avenue leading to the lake, by the side of which there is a curious group of Horse Chestnuts growing in the most grotesque manner. Their branches upon touching the ground curve like a hoop, and shoot up again perpendicularly with increased vigour, which forms a very interesting spectacle by the side of the lake. Whether the branches have been "layered" or have rooted of their own accord there does not appear to be any record, but to the practical eye the "curve" is too neatly formed to be of spontaneous growth. The conservatory is an old-fashioned structure with glass domes, and contains Tree Ferns, Orange trees, Camellias, and Myrtles. By the way, what a pity the latter are not more grown for the embellishment of such structures. The pyramids in the conservatory of Lowther Castle would tempt any one into growing Myrtles either for adorning conservatories in winter, or for turning out-of-doors in summer. From the front of the conservatory a pleasant peep is obtained of the lake, and also of several fine Chestnuts, Cedars, and Weeping Willows by the side of the lake. The fancy ducks of American breed are also very attractive upon the lake.

The kitchen gardens at Milton are extensive, the principal one enclosed by walls being over 4 acres, besides two or more smaller ones equally productive. The walled-in garden is cut in two by a central broad walk. The garden was entered by the south-east side, and at first sight you can see that order and skill are not wanting in its management. There is nothing untidy, nothing out of place, whether it be fruit trees, vegetables, or plants, of which many are grown in the long borders fronting the houses. The south-east wall is stocked with healthy Peach trees in bearing. Apricots are upon the north-west and west walls, and Plums upon the east wall. The ranges of glass structures are, of course, upon the south

wall. Mr. Trigger grows herbaceous plants extensively, and arranges them effectively. Perhaps there are few places where the same extent of borders are so well arranged with hardy plants, of which the following are the most striking and useful:—*Monarda didyma*, *Salvia glutinosa*, *Statice latifolia*, *S. incana*, *Enothera macrocarpa*, *Echilobium angustifolium album* and *roseum*, *Echinops striatus*, *Veratrum nigrum*, *Funkia grandiflora*, *F. ovata*; *Geranium sanguineum*, *striatum*, and *pratense*; *Galega officinalis*, *Clematis integrifolia* and *C. integrifolia erecta*, the lovely *Bocconia cordata*, *Tritoma aurea*, *Veronica longifolia*, *Tradescantia virginica*, *Hemerocallis flava* and *H. fulva*, and many others of less note and not so useful for practical purposes. The rock garden at Milton is more than the majority of things called by that name in most private places, and which unfortunately are often mere rocks or roots than plants either of interest to the plant lover or of utility to the practical gardener. Mr. Trigger has the hardy Ferns neatly arranged, legibly named, and in good health, so that if you are at all up in plant nomenclature you can read, judge, and admire for yourself to your heart's content. There are many Saxifages and other alpine plants in other parts of the rock garden, all of which succeed well and are showy during the spring months, when outside flowers are of all other seasons the most welcome and beautiful. The garden in which the rockery is located is enclosed upon the east side by a Yew hedge 15 feet high, which is a striking sight even now before a leaf has fallen, but which is much more handsome when deciduous trees are naked and there are few other counter attractions.

In the glass structures I noticed the fruit department was particularly well done; the early crops were at the time of my visit gathered, but the trees and plants of all kinds were in the most vigorous health, the Peach trees especially being unusually healthy and well grown. Mr. Trigger grows a nice collection of Orchids in the plant stove, and neither stove plants nor Orchids seem to be any the worse for each other's company. The plain fact is that Orchids can be grown with ordinary intelligence and care anywhere. The following list, grown in conjunction with stove plants, will serve to illustrate the accommodating nature of Orchids, and the simple conditions under which a great many species may be cultivated:—*Vanda teres*, *V. gigantea*, *V. tricolor*, and *V. insignis*; *Cattleya Skinneri*, *C. crispata*, *C. Trianae*, and *C. Mossiae*; *Coclogyis cristata* and *C. barbata*, *Calanthe Veitchii*, *C. vestita*, *roseana* and *C. Turnerii*; *Laelia anceps* and *L. Dayana*, *Trichopilia suavis*, *Arculis odoratum*, *Sobralia macrantha*, *Dendrobium Dalhousianum*, *D. Wardianum*, *D. densiflorum*, *D. thyrsiflorum*, *D. macrophyllum*, *D. leviomanum*, *D. heterocarpum*, and *Anselia africana*. Of course these are but a few of the best plants, many of which are approaching to specimen size, and are in a strong flowering condition. The stove plants that seemed worthy of mention consist of *Pandanus utilis*, *Cycas revoluta*, *Pancretium fragrans*, *Alpinia nutans*, *Strelitzia regina*, several Palms, *Dracenas*, *Crotons*, and other tropical plants, favourite kinds grown for special private purposes. The Rose-house is one of the most interesting structures upon the place, and although the plants were at rest it was clear from their condition that the time was not far distant when they would supply those rich treasures which are ever the product of a well-managed Rose-house, viz., cut Roses from November to March, after which the stock is plentiful enough everywhere. The greenhouse and show-house were gay with flowering *Begonias*, *Celosias*, *Pelargoniums*, *Balsams*, *Petunias*, and *Fuchsias*; and smaller structures were stocked with winter-flowering plants in quantities. Cucumbers and Melons are grown in span-roofed houses; and Tomatoes, a very fine strain, are grown upon every available foot of wall from 1 to 3 feet high. The crops of hardy fruits were plentiful, and vegetables of all kinds successfully grown in every quarter of the garden. Of vegetables a selection of Dell's Beet was a splendid crop of roots, such a strain as would be worth perpetuating, and which should be brought prominently into public notice. The various garden offices are commodious and in good order, even the compost ground and kindred places indispensable in a garden are each and all kept neat and tidy—and as it is a pleasure to inspect the cultural condition of the garden so it is an equal pleasure to note the system upon which the general management of the garden is conducted under the guidance of an able and intelligent practitioner, who succeeds with everything he undertakes in a manner that leaves nothing more to be desired. *Reporter.*

DEW AND HOAR FROST.

ALL plants require moisture in order to live and grow, and Nature has provided in the abundant supply of this element one of the principal factors which determine the greater or less vigour of the growth of plants upon the earth.

It is to the copious dews that we have in a great measure to attribute the productiveness of the meadows bordered by rivers.

Water covers about three-fourths of the surface of the globe as ocean, partly in a solid condition, as at the extreme north; partly fluid, as in all warmer regions; it flows through the land in all directions in the form of rivers; it ascends into the air as vapour, and falls again to the earth as rain, snow, or dew. This continuous circulation of "water" produced by "heat," is the especial agent which penetrates the earth, filling it with life and prosperity.

Where water exists the sandy desert changes into a luxuriant oasis; where it is absent, even the greatest richness of soil remains a "waste," and unproductive.

Dew, which forms our particular subject, is the humidity which the air under certain circumstances deposits in the form of minute water globules on the surfaces of the bodies in contact with it. For instance, on the withdrawal of the sun's rays the atmospheric air becomes colder, consequently the blades of grass, and leaves of plants become chilled from exposure to the influence of the cold, and in their turn cool the damp air which touches them, and cause it to drop its moisture upon their exposed surface. When the condensation of vapours occurs by contact with cold solid bodies it is called "dew;" when, on the contrary, the whole body of air is cooled, "mists," "clouds," or "rain" is formed. It is probable that if it were not for the effect of dew the rapid escape of heat from the earth by radiation, the temperature of the soil would become so depressed during the sun's absence, that the extremes of heat and cold in the course of twenty-four hours might be so great as to destroy vegetable life in the summer season; and it is generally after nights of copious depositions of dew that the mornings are the brightest, and the sun's heat the most powerful.

Dew is only formed beneath a calm and cloudless sky, and never in windy weather, for under the influence of wind the moisture of the earth is carried off with extreme rapidity. A north wind also checks its production, but a gentle southerly breeze, charged with humidity, will occasion a copious deposit. When the atmosphere has a temperature below the point of congelation, the dew, which might adhere to the substances exposed, passes into the form of hoar frost. It is also found that if the temperature of the earth's surface sinks during the night down to freezing point, the particles of water deposited become solid and form hoar frost.

A deposit exactly similar to dew is formed whenever the air becomes suddenly chilled, by touching any surface colder than itself. Thus the walls of long passages, vaults, or massive buildings generally, drip with wet during the early part of the summer, before the external warmth has sufficiently penetrated.

Leslie says—"In fine, calm weather, after the rays of the declining sun have ceased to warm the surface of the ground, the descent of the higher mass of air gradually chills the undermost stratum, and disposes it to dampness, till their continued intermixture produces a fog or low cloud. Such fogs are, towards evening, often observed gathering in narrow valleys or along the course of rivers, and generally hovering within a few inches of the surface."

In clear and calm weather the air is always drier near the earth's surface during the day than at a certain height above the ground, but it becomes damper on the approach of evening; hence, dew is always more dense on grass and low-growing plants than on the leaves of shrubs which stand up some feet from the ground.

Many substances are endowed with the property of radiating their heat, and of thus becoming cool with different degrees of rapidity, and it is found that those substances which in the air become cool first, also attract the most quickly and abundantly the particles of falling dew.

Dr. Wells in his observations on the deposition of dew found that grass became 12° colder than ordinary garden mould, and 16½° colder than a hard gravel-walk; hence we find that dew deposits the most readily on living vegetation, and that well-pulverised soils draw more dew than those which have a

hard surface, and are close and compact. Wherever the atmospheric air can freely penetrate there the depositions of dew under favourable circumstances take place. Sandy soils are powerful attractors of moisture, and on the sandy plains of Chili, where rain is scarcely ever known to fall, vegetation depends almost entirely on the nightly depositions of dew for its support.

It has been estimated by Dalton that the amount of dew which is annually deposited upon the soil amounts to about 5 inches, equal to more than 500 tons of water per acre. But the meteorological records inform us that the yearly rainfall on the eastern side of our island amounts to about 25 inches, while 40 inches, or nearly double the quantity, is precipitated on the western side; and, as we find the rainfall varying considerably at different seasons and in different localities, so we know it is in the case of dew.

Steinmetz remarks that "the quantity of aqueous vapour in the atmosphere is greatest in equal latitudes on the sea-coast; it diminishes in proportion as we advance into the interior of a continent." In Algeria, at the stations on the coast, after the driest and hottest days, immediately the sun has set the soldiers' uniforms become wet with dew, and in a single night the blades of knives in the pocket become rusted, but at 30 miles from the sea night exposure is not attended with any inconvenience from the humidity of the air.

In countries near the equator the depositions of dew are much more abundant than in England, owing to the greater amount of heat absorbed from the sun during the burning heat of the day.

The quantity of vapour which the air is capable of holding in suspension is dependent upon the temperature, and we always find the atmosphere in the vicinity of currents of water more highly charged with moisture than it is in the uplands. In India the deposition of dew near the rivulets when all around is perfectly dry is said to be exceedingly marked. Colonel Sykes observes that "When in Poona in September and October, 1850, if there was no dew anywhere else it was found on the banks of rivulets and the Mota Mola river, but 15 to 20 feet from the water were the limits of the deposition."

Turning now to the composition of rain, dew, and hoar-frost, Boussingault has given the following analyses of samples collected at Paris and Liebfrauenberg in the year 1853:—

Table 1.—Showing the Composition of Rain, Dew, and Hoar-frost, in Grains per Imperial Gallon.

	Ammonia.	Nitric Acid.	Total Nitrogen.
Rain { Paris	0.210	0.0788	0.2888
{ Liebfrauenberg .. .	0.2159	0.1440	0.3600
Dew { Liebfrauenberg } Maximum .. .	0.4310	0.0755	0.5065
{ } Minimum .. .	0.0744	0.0030	0.0774
Hoar-frost { Paris	0.9600	0.7092	16.3092
{ Liebfrauenberg .. .	0.1711	0.0716	0.2427

It thus appears that in Paris the quantity of nitrogenous matter brought down in the rain-water is six times as great as it is in the country (Liebfrauenberg), a result no doubt due to the ammonia evolved during the combustion of fuel and to animal exhalations; and to the same cause may be attributed the excessive quantity of nitrogen found in the fogs of Paris. We also observe that dew is richer in plant-food than rain, which may serve to some extent to explain its remarkably invigorating effect on vegetation.

Again, Lawes, Gilbert, and Warington have lately published in the *Journal of the Royal Agricultural Society* the following analyses of rain, dew, and hoar-frost collected at Rothamsted, and determined by Dr. Frankland.

Table II.—Showing the Maximum, Minimum, and Mean Amounts of Certain Constituents in Sixty-nine Samples of Atmosphere collected at Rothamsted, in parts per million.

	Total Solid Matter.	Carbonic Acid.	Organic Matter.	Nitrogen as			
				Ammonia.	Nitrates and Nitrates.	Total Nitrogen.	Chlorine.
Highest proportion ..	85.1	17.9	0.04	0.03	0.14	1.04	10.5
Lowest proportion ..	6.0	2.1	0.03	0.04	0.01	0.1	0.0
Mean sixty-nine samples ..	31.7	0.02	0.10	0.17	0.07	0.24	2.1

Vol. XXVI, pt. 1. Mean of thirty-four analyses.

Table III.—Showing the Maximum, Minimum, and Mean Amounts of Certain Constituents in Sixteen Samples of Dew and Hoar Frost, Collected at Rothamsted, in parts per million.

	Total Solid Matter.	Carbonic Acid.	Organic Matter.	Nitrogen as			
				Ammonia.	Nitrates and Nitrates.	Total Nitrogen.	Chlorine.
Highest proportion ..	30.0	1.50	1.06	2.51	0.59	4.55	8.0
Lowest proportion ..	26.4	1.95	0.26	0.47	0.28	1.66	3.5
Mean, seven samples ..	18.7	0.64	0.76	1.53	0.46*	2.79	5.3

In the analyses by Boussingault of aqueous deposits collected at Liebfrauenberg we find that dews are twice as rich in nitrogenous compounds as rain-water, while at Rothamsted, from analyses made by Dr. Frankland by improved methods, nearly twenty years later, we find that these small deposits condensed from the lower stratum of the atmosphere contain on an average three or four times the amount of organic carbon, organic nitrogen, ammonia, and nitric acid found in the analyses of rain-water. The total quantity of solid matter and the amount of chlorides is also larger, but the difference is much smaller than in the case of the other ingredients.

It may be asked why snow and hoar-frost should be white? The question is a natural one, but the answer is easily given. If snow had been black it would have rapidly absorbed the sun's rays and been thawed by the first sunshine which fell upon it, the result of which would have been that vegetation, being prematurely deprived of that protection which Nature intended to guard it against the cold, would have died in the frosty air as soon as the sun had set. But the heat-reflecting and non-conducting "white snow" and "hoar-frost" are of the utmost importance as a protection against sudden alterations of heat or cold, for while it is melting its temperature never varies from 32° Fahr., and the plants which are enveloped in it rarely suffer a much lower, and cannot be exposed to a higher temperature. Hence we observe that frosts in spring or in early autumn generally do more damage to vegetation than the prolonged frost and excessive cold of winter, because the sun's rays act quickly upon the unprotected frozen plants, and by a sudden alteration in their warmth induce a change inconsistent with their vitality. Therefore gardeners during the winter season should take as much care to protect their plants from the sun's heat as from the frost's cold. J. J. W., Harpenden, February, 1882.

PLANT PORTRAITS.

BATAFAS PANCULATA, Garden, December 24.—A very handsome stove twiner, with deeply palmately lobed leaves with narrow segments and pink funnel-shaped flowers of large size and great beauty. Hort. Kew.

BEGONIA DAVIESII (double-flowered), Floral Mag., t. 477.—A fine double red, symmetrically formed flower. Messrs. Laing & Co.

CARNATION CHISWICK RED, Floral Mag., t. 480.—A Clove Pink, with small, very brilliant red flowers of medium size, good form, and very fragrant. Raised at Chiswick.

CHRYSANTHEMUM (NODORUM FL.) PLENO, Garden, t. 1055.—A reproduction, unacknowledged, of our figure at p. 753, vol. xii.

ODONTOGLOSSUM YENILLIKURUM, Belg. Hort. t. 14, 1880; Rehl. t. Gard. Chron. 1867, p. 901.—Figured in 1873, p. 644.

ONCHICUM WELTONI STERUM, Rev. Hort. December 1.—A fine variety, with a denser and more compact spike than usual.

OPUNTIA KAFINESQUI, Garden, Dec. 3.

PEACH BELLE IMPERIAL, Bull. d'Arboriculture, December, 1881.—A first-class late Peach of large size, fine colour, and vinous flavour. It originated at Montreuil in the garden of M. Chevalier, but nothing is said as to the character of the glands, size of flower, or nature of stone.

VERISIA SCALARIS, Ed. Moit., Belg. Hort. t. 15, 1881.—An epiphyll Bromeliad, with tufted leaves, broad at the base, narrowing into a stalk, and again expanded into an oblong lanceolate serrulate blade. The inflorescence is spiral, pendulous, the flowers remote one from the other, and spreading horizontally, so as to give the appearance of a ladder, whence the name. The individual flowers are long, cylindrical, yellow flowers, emerging from scarlet bracts.

* Mean of four analyses.

HOME CORRESPONDENCE.

New Sorts of Potatoes.—I am anxious to get a complete list of all the kinds of Potatoes offered in commerce for the first time this season in Great Britain. I have already called from your advertising columns and other sources some twenty kinds, but am not sure whether there are not others not yet publicly mentioned. I think it will be found that the present year is the most prolific one of new kinds that has yet been known, and as a "Potatologist" I am very glad of it, because evidence is thus afforded that, so far from public interest in the Potato being on the wane, it is greatly on the increase. I am very hopeful, too, that many of the new kinds are really first-class acquisitions, and will make their mark. Although I am not authorised to say as much, yet it is just possible that the class for kinds of recent introduction in the next schedule of the International Potato show will, because of the large number of new kinds, and also because these are excluded from specially named classes, be increased to six sorts, and be confined to those sent out for the first time this year. Whether this arrangement be adopted or not at least all exhibitors will be pleased to learn what are the new kinds eligible for the competition. In any case I anticipate in that class a much larger competition than usual, and so highly do I think of many of the new sorts as exhibition kinds that I believe it will be easy to get from them half-a-dozen sorts that should hold their own in any competition. Any information from raisers of the trade would be thankfully received. *Alx. Dean, Bedford, Hounslow, W.*

Peziza coccinea.—This beautiful little fungus will keep its colour and last for months in a London drawing-room, if placed under a glass shade and kept moist. I gave some to a friend a few years ago, together with some of the Hampshire children call "the feather-moss," and was astonished to see all looking bright and fresh in Miss B.—'s room full three months afterwards, when I went up to London to stay with her. She had placed moss and fungi in a shallow dish on a little mould, and covered them with a glass shade. *Helen E. Watney, Lis.*

Pulmonarias.—The charming *Pulmonaria saccharata grandiflora* alluded to at p. 226, has been in bloom here in the open ground for the past fortnight, and well ranks amongst the hardest of hardy plants. Very singular indeed is the change of hue which takes place in its blossoms, for they are both bright red and bright blue on the same bunch, indeed I can liken them to nothing so much as red and blue Pimpernels, so pretty are they and yet so strangely contrasting. This *Pulmonaria* is too robust for rockwork except where it has ample leaf space and root room, for the roots will strike deep and wide. It makes a fine clump in a mixed border, especially where during the summer and autumn months it displays a fine marbled foliage as well as its large and finely marked terminal I think this has the handsomest foliage. It is but one of many hardy plants sold met with in gardens, and is, as too many hardy plants are, but little known. The peculiar floral passions of the age, in spite of what has been done to set them in a right direction, do not yet favour the growth of hardy plants. Five guineas is perhaps more often paid for a fashionable Orchid than for a hundred beautiful hardy plants; still worse, gardeners give them too little attention. Probably most of them are demanded more of all other departments than they do of hardy plants. *A. D.*

Confers Attacked by Fungus.—Our *Thuyas*—especially *Thuya aurea* and *elanitisima*—have for some time been covered with a parasite which rapidly proves fatal to them. I enclose you a sample of it, and shall feel much obliged if you will tell us its name, the reason of its appearance, if you are able, and also by what means we can most effectually rid ourselves from it, and prevent its visits in future. Destroying our correspondent's *Thuyas* is *Capnodium australe*, a close ally of *C. Footii*, so frequently sent us on Ivy, Laurels, and other evergreens. In some instances, but not in the present, this destructive fungus is associated with scale insects. *W. G. Smith.*

The Cyclamen.—The treatment required by this useful plant has often been explained, but as there are comparatively few private places where convenience exists for giving it exactly the treatment usually recommended, a short account of the system by which I have been fairly successful may be useful to some. The seed is sown in spring, not earlier than

March; the pan is placed in the stove until the plants are up, then removed to a vinery where the fruit is swelling. As soon as the corns are about the size of a Pea, they are pricked out about 2 inches apart in other pans, and when established removed to the greenhouse for a short time, and about the beginning of June to a cold frame. The frame occupies a sunny position, but is shaded from bright sunshine with tiffany; plenty of air is given throughout the day, but the plants are damped overhead and the frame closed early in the afternoon of bright days. Before the plants become overcrowded they are potted singly in 3-inch pots, the soil used fibrous loam, a little leaf-mould, rotten manure, and sharp sand. Though an advocate of firm potting for most things, I find that the Cyclamen and many other plants with thick roots do best when potted only moderately firm. During the month of August the lights are drawn off at night, to give the plants the benefit of the heavy dews; and in September they are kept off day and night. The plants are removed to a span-roof greenhouse about the beginning of October; this house contains a mixed collection of plants, so cannot be kept very warm; but the Cyclamens are placed at the warmest end, and in dull damp weather the pipes are just warmed every day, and the ventilators opened a little. From seed sown last March have corns an inch or more in diameter, and bearing from twenty to thirty flowers; they will be potted in 5-inch pots in a week or two, and remain in the greenhouse until the beginning of June, when they will be put in a frame and treated the same as last season. The full exposure in September is important in preparing the plants for wintering in a rather low temperature, and is also conducive to a free blooming disposition. This year mine were taken to a cold conservatory in good condition the first week in January, a little earlier than usual, owing most likely to the unusually large amount of sunshine in the early part of the winter. After flowering the plants are put in a cold frame, and about the end of April stood outdoors in a shady place; they are never allowed to become very dry at the root. Early in June they are turned out, the balls reduced, potted in 7-inch pots, and put in a frame to grow on, all the stock of this year being withered little or not at all. The beginning of June is earlier than often advised for potting old plants; but under cool treatment it is necessary, in order to have growth completed and flower-buds showing before colder weather sets in. *W. Crane, Quarterton Park, Co. Cork.*

Tecophilæa cyanocrocus and Leichtlini.—Like my friend Mr. Harpur-Crewe, I also got three bulbs of the above-named most lovely of blue-flowered spring-flowering bulbs in the course of last autumn from Herr Max Leichtlin, of Baden (one of the deep blue type and two of the turquoise variety, with purple throats), these are all now in full and beautiful bloom in a pot in my greenhouse, and are the admiration of every one who sees them; alongside of their large and more exquisitely coloured flowers the pretty little *Chionodoxa Lucillie* must hide its diminished head. When these bulbs came to me from Baden I was warned by Herr Leichtlin that being perfectly hardy (and having withstood a frost of 5° below zero in his garden in the open air without any protection and without sheltering in any way therefrom) they would grow without any attempt to cosset or force them in order to flower them successfully; I therefore plunged the pot in which I had planted them in a narrow border close to a low garden wall on the south side, where they remained the whole winter and till the plants were an inch above-ground, when, finding the slugs beginning to pay them attention, I lifted the pot into the greenhouse, where the blooms expanded early in this month. Each bulb made two stems, and the deep blue form (or type) has the larger and the lighter blue variety seven. They seem, however, to vary considerably both in size and substance of flower and in depth of colouring, as Mr. Crewe describes his flower in your last issue as with a distinct white throat, whereas mine is of the deepest gentian blue with only the faintest white lining towards centre; and in the paler variety the flowers of one of my bulbs is much thinner and less perfect than the other, and would be almost more correctly described as a white flower with pale blue tints to the corals, whereas the other bulb is distinctly blue flower with pure white throat. Herr Leichtlin says the flowers of his variety should be nearly twice the size of those of the type when the plant is grown altogether in the open air, but with me they are both about the same size. *W. E. Gumbilton.*

Mice in Gardens.—At different times, for some years past, these destructive animals have done much mischief in the garden here. We have five kinds, each one doing his share of mischief at different seasons, and in various ways. They are the house or barn mouse, the long-tailed field mouse, the short-tailed, called here the badger-mouse; the small black

mouse with long nose, which is not so troublesome as the former kinds; and last, but not least, the sleeper, or dormouse, which only comes in the summer season—but the mischief he does in a few hours is almost incalculable, either amongst nuts or wall fruit, such as Apple-trees, Peas, Flums, Cherries, &c. As he works by daylight, a careful watch will trace out his path in the tree, when a small iron trap, called here clams, baited with a nut, will soon tempt him to his destruction. The two first are very fond of the seeds of Peas, Beans, Radishes, and all the Brassica tribe, after sowing. Both the long and short tail kinds are very destructive to young Cauliflowers, Lettuce, Endive, and Finks, in cold frames. This season they have barked the stems of Broccoli, some being eaten through the crown; others have the young leaves eaten out at the heart. In summer they visit the Peas when fit to gather and young Potatoes in the ground. One season, the ground being covered deeply with snow, they burrowed under the Seakale and Rhubarb pots, eating out the crowns and damaging the crop to a great extent. I always use the same trap and bait as mentioned before, and catch them by day and night, having lately killed a great number. I have no doubt those who are troubled with these pests can do the same. The traps can be had at any ironmonger's at a cheap rate. I also use the same trap and bait for small birds in the seed-beds, &c. The "Perpetual Mouse-trap," mentioned at p. 229, is very good for the common mouse, but those that feed on herbage are not so easily tempted to enter in. *Wm. Divers, Winton House, Maidstone, Feb. 20.*

Protecting the Blossoms of Fruit Trees.—Now that the time for taking action in the matter of protecting the blossoms of our choice fruit trees from the effects of frost, with a view to securing crops of fruit therefrom, is near at hand, a word or two respecting the next best material to glass for this purpose may be acceptable to those of your readers who may now, with this object in view, be contemplating the protecting of their fruit trees, but find it difficult to decide upon the best material with which to protect them. To those I wish to say, day and night, having lately killed a great number. I have no doubt those who are troubled with these pests can do the same. The traps can be had at any ironmonger's at a cheap rate. I also use the same trap and bait for small birds in the seed-beds, &c. The "Perpetual Mouse-trap," mentioned at p. 229, is very good for the common mouse, but those that feed on herbage are not so easily tempted to enter in. *Wm. Divers, Winton House, Maidstone, Feb. 20.*

Ants in the Peach-house.—One day last week I was surprised to see that several of the Peach bushes, in one of the houses here, were without pistils, and found on investigation that the ants had eaten off the pistils just above the ovary as described by Mr. Horace Woods. We have been diligently pursuing a war of extermination against the ants for some time, by placing treacle in the vicinity of their haunts to attract them—round which the antler in hundreds—then scalding them with hot water. By this means we have succeeded in diminishing their numbers considerably. *J. Riddell, Wotton, Kentham.*

—When visiting Manresa Gardens, Kooheampton, in February last year, Mr. Davis drew my attention to several Peach-blossoms, the pistils of which had been destroyed by ants. A narrow strip of canvas was tied around the stems of each tree, near the ground, and painted occasionally, which had the effect of keeping the ants off. *S. P., Chelmsford.*

Potato Beauty of Hebron.—I am pleased to see this Potato is to some extent gaining favour amongst growers. I think, when its merits become more generally known, it will receive a corresponding share of patronage both for the garden as well as field culture. In my opinion it is one of the best—if not the best—of all the American introductions. No one, I think, can deny its extraordinary productiveness, and very few, I venture to say, can dispute its excellent cooking properties. Another great feature in its favour is, being a moderate early variety, it is less liable to the attack of the disease. The fact of its frequent appearance on the exhibition table also bears sufficient testimony to its adaptability for this purpose. My advice, therefore, to all intending planters is, to plant the Beauty of Hebron largely, and not in limited quantities, as decided upon by "A. L. II." (see p. 228). The result will, I feel confident, give every satisfaction. *E. Morgan, The Butts, Harrow-on-the-Hill.*

Storing Ice Above-ground in Sawdust or Sawdust Pits.—The antiquity of the plan of storing ice above-ground in sawdust is of little consequence, seeing that the system, when properly carried out, is so thoroughly successful; but as I have been the means of bringing the subject under the notice of

your readers in January, 1876, and again in your issue of the 4th inst., I would like to be allowed to remove the obstacle—the only and not very formidable one—that Mr. Melville, at p. 229, attempts to place in the way of the system being generally practised—a system which, as it becomes better known, will supersede every other mode of preserving ice; even the sawdust and wooded wall pits will have to give way to it, seeing that the same object for which it was deemed necessary to expend £25 in the making of the latter to secure is achieved by resorting to the “above-ground system” without the spending of a single penny in that direction. And this fact must not be lost sight of, inasmuch as it is, together with the extra labour incurred in getting the ice out of the pit, the only difference between the two systems, both of which answer their primary purpose equally well.

Respecting the obstacle in the way of the valley (referred to at p. 154 of your current volume), and of which Mr. Melville, writing from the lofty slopes of Dunrobin, is uneasy on the score of there not being always one at hand, a circumstance to the writer unknown to exist in the demesnes of establishments requiring a supply of ice the year through. It certainly does not exist at Dunrobin, for Mr. Melville tells us in your number for January 14, p. 45, that “The site selected for the pit was near the kitchen and larders, in the wood near the Castle, partially shaded, and with a northern exposure, while a rise of the ground to one side admitted of carrying the height above the level of the pit, so as to tip the ice down a shoot directly into it, while a hollow near by secured an outlet for a drain at any depth necessary.” Thus it will be seen that the situation selected for the formation of the “sawdust-pit” was admirably adapted for an “ice-stack,” or a rick, the latter being quite as suitable as the former—and, indeed, preferable, inasmuch as it obviates the question of insufficient slope arising to obstruct the system coming into general practice. Moreover, the rick, as a matter of course, should be made sufficiently long to compensate for loss sustained through deficiency of height. In conclusion, I beg to assure those of your readers who may feel disposed to give the “above-ground system”—a system which has everything to commend itself to general use—a trial, that by faithfully following the instructions given in the *Gardeners' Chronicle* for February 4 (p. 154) of the present volume respecting the process of preserving ice in sawdust above-ground as practised here success will be attained. I would further add that there is a right and a wrong way of doing everything, and it would appear that “storing ice above-ground” is no exception to the rule, for Mr. Melville tells us of his having heard of it succeeding in one place and utterly failing in another—a circumstance which fully demonstrates the fact of the procedure in the latter case being at fault, and that *mutatis mutandis* in the *modus operandi*, consequent upon the subject being described in the pages of this journal, better results may be looked for in the future. *H. W. Ward, Longford Castle, Wells.*

Florists' Flowers.

CYCLAMENS AT TWICKENHAM.—The superb lots of Cyclamens shown both at South Kensington and elsewhere by Mr. Clarke, of Twickenham, during the present winter have plainly shown that just now that grower occupies a leading position as a cultivator of this beautiful winter flower. It would seem, after all, that there must be either some special skill required for the successful cultivation of the Cyclamen, or else that there is particular virtue in particular places, for not only are the growers of this flower for market limited in number, but all, or nearly all, reside on the west side of London. Although just now Mr. Clarke doubtless has first place as a Cyclamen grower, it is as certain that but a year or two since his plants did not excel those grown by Mr. H. B. Smith, of Ealing, and who has yet a fine strain, especially of pure whites. Mr. Pestridge, of Brentford, and Mr. Walker, of Whitton, are both well known and large growers of “Sykes,” as they are best known in market phreology, and these, we believe, are the chief market men who devote themselves specially to their culture. All of these, it will thus be seen, are West Middlesex men, so that we may be pardoned for assuming that there is something in the air of that district which favours the Cyclamen.

The extraordinary voracity of the London plant market is well shown in connection with the Cyc-

men, for it annually swallows up tens of thousands; indeed, Mr. Clarke, who is certainly a large grower, annually disposes of some 20,000 in one way or another—an enormous quantity, certainly, to go out from one establishment. In spite of this large trade Mr. Clarke's nursery is of a very modest kind, for it is enclosed with high walls, and invites no public attention; indeed, market growing establishments seldom invite visitors, neither are they wanted—they are literally plant manufactories for the retail trade, and have no other show-rooms than are to be found in the London flower-market. The houses and pits in which the bulk of the plants are grown are far from being modern; indeed have in years past been devoted to the growth of Vines and Lines, but have now been converted to their present uses by the introduction of stages lifting the plants up near to the glass, where they get plenty of light and air. The only modern house—a lean-to of some 125 feet in length, having in front a broad stage, and behind a stage in rising tiers—is the showhouse, if such a term is applicable, for here are seen all the plants selected for seed stocks, and a grand lot they are. The front stage is occupied almost throughout with splendid plants in 2½ or 7-inch pots in grand bloom—indeed, there must be many hundreds of them. These are all robust seedlings blooming for the first time from a sowing in August, 1880, and would astonish novices in the art of Cyclamen culture. The enormous quantity of bloom produced on a single plant is quite remarkable. Many that have been in bloom since November, and have even now perhaps fifty to sixty blooms open, are yet almost a mass of flower-buds, and will in a cool-house continue to bloom till well into May; so that strong plants of the Cyclamen will do what few other plants will do—bloom continuously for six months, and those from November to May. The great bulk of the market plants are in 48's, the regulation size, but the larger plants are only sold to special orders.

Seed is usually sown early in August, in 6-inch pots, about fifty seeds in a pot. These pots are stood on stages in the pits that keep them within 6 inches of the glass, but no artificial heat is needed to promote germination. On warm sunny days a little shading is given. Seedlings, when strong enough, are pricked up into other 6-inch pots in dozens, and from these are later on transferred into small 60's, then again into 48's, and the most robust and promising into 32's, and finally into 24's. Very gradual shifts are found best, as the roots sooner reach the sides of the pot. Large shifts would perhaps result in sodden soil, and then root-rot.

The most suitable compost for the Cyclamen is found to be two-thirds of sweet fibry loam, and the rest of well-decayed leaf-soil made from clean park leaves. Plants sowed for seed, however, do not depend alone upon their seed-crop for profit, as the blooms are pulled and bunched in dozens for market, and their fine quality invariably brings a good price. Plants of the new Giganteum compactum strain have blooms of great size; a sample bloom had petals 2 inches in depth and 4 inch across, the plants full of bloom, and the habit all that can be desired. Although this habit runs through the whole strain, the Giganteum compactum strain has mostly white blooms with a deep purple or crimson base; the rubrum flowers, deep mauve, are of similar size. There are pure whites of fine form and substance, and one form, known as Delicata, pure white with a delicate tinted base, is a charming kind. The rose tints are singularly bright and cheerful. These vary more or less in shading, but all are very beautiful. A grand kind indeed is Crimson Gem, the colour deep red, a very fast colour, and flowers produced in marvellous abundance. This is one of the best deep-coloured forms we have seen. Brilliant, an older form, has smaller and deeper-coloured blooms, but they are small. The best purple, perhaps, seen, unlike the general run of this colour, has bloom of a very fast hue, the colour deepening with age to violet. This hue is not, however, favoured amongst market growers, and therefore it is not largely perpetuated; whites, roses, and rich reds are the favourite colours.

With a general clearance of the Cyclamens room is made for Strawberry plants in 24's, all just now housed for the winter in frames. None are forced early, but just soon enough to lead up to the incoming of the outdoor crop, the plants to produce which are all pot plants turned out and standing two years only. Mr. Clarke's Strawberries are of the finest that go to the London market.

NAMED CINERARIAS.—It is pleasant to see that some of these still find a place in catalogues, some of them, of the best quality, illustrating to a great extent the presence of the high qualities of form, colour, and arrangement that were so strongly insisted on twenty years ago. We are just now in great danger of being

encumbered with a race of large-flowered Cinerarias, in which size is the most striking feature, but in which symmetry, substance, and finish are to a large extent absent. There is any amount of floral ugliness, and we see large, staring white-ground flowers, with pale and grey discs, that would not have been tolerated years ago. The toil the last generation of florists underwent, and the patience with which they worked to secure—and did succeed in securing—certain desired ends, appear to be in danger of being forgotten in the desire to have something of what is termed decorative value. Mr. Shirley Hibberd has recently been laying down the principle that mere novelty in plants and flowers should be subordinated to merit, and in stating this much he is in harmony with the floral teaching of our forefathers. It is time some one made a new departure with Cinerarias, harking back to the old lines, and gradually working up to a high ideal. For a time his efforts may be frowned upon or misunderstood, but the day will surely come when his work will be appreciated, and his labours rewarded. We have had enough of large star-shaped Cinerarias with pointed petals and clouded colours; it is time they made way for something better, possessing the refinement that lends such a charm to other qualities. The opportunity offers now—where is the man to avail himself of it? *R. D.*

HARDY CLEMATISES.—These, which are always early in starting into growth, have been most active all through the winter; indeed, almost as soon as last year's leaves began to decay the buds out of which have to come the spring shoots were plumping up. In the case of strong established plants it will always be noticed that growth is put forth at the points of the ripened wood farthest from the roots. It is best, on the whole, not to cut this away in the autumn or winter, but to leave it till February before the cutting back process is attempted. In the case of Clematises grown in beds it is sometimes necessary, in the interests of tidiness, to cut back earlier, but we are stating a generally acceptable rule. Our plan is to cut back almost to the ground, then to draw the soil away from the roots, add a good dressing of manure, and return the soil to the surface. In a short time the plants break into a vigorous growth, and if it is desired to cover a given space the young shoots should be trained in position or they will become interlocked with each other, and the growth be concentrated instead of being distributed. As a matter of course the foregoing remarks apply to what is known as the strong summer flowering varieties of the Jackmanni type. Of these the following can be highly recommended:—Alexandra, pale reddish-violet; Jackmanni, deep violet-purple; Rubella, velvety claret-purple; rubro violacea, maroon shaded violet; Star of India, reddish-violet purple; The Shah, deep lavender, changing to lilac, and turgidness; deep bluish-purple. The best white flowered variety to add to these would be *lanuginosa nivea*; and the best pale blue, *Lady Bovill*.

The Apiary.

YOUR correspondent, “Busy Bee,” says, “With such a winter as is the present one there should be a good honey harvest.” May I ask the reason why? Having quite recently received a letter from a gentleman who has kept bees for a quarter of a century and is considered as an authority, in which he writes thus:—“Bees will be in a bad way shortly—mind that!” In the *Bee Journal* for February it is thus written:—“And within the beehive a forward state of things that cannot be considered wholesome or safe.”

“Or the chill blast from Eurus' mildew wing.

Light the fair promise of returning spring;

Full many a hive, but late and early,

Droops in the lap of all-inspiring May.”

North Norfolk.

BRITISH BEE-KEEPERS' ASSOCIATION.—The annual general meeting of the members was held in the board-room of the Royal Society for the Prevention of Cruelty to Animals, on Wednesday, 15th inst. There was a large attendance of members, including several ladies. The chair was taken by the Baroness Burdett-Coutts, the President of the Association, in the absence of the Rev. H. N. Peel, the Honorary Secretary. The report for the past year was read by Mr. T. W. Cowan, the chairman of the

committee. The report gave an excellent résumé of the Association's work during the past year, from which we learn that the subject of bee-keeping is being now much more extensively supported by many of the leading agricultural and horticultural societies than in former years.

— Died suddenly, on the 15th inst., at Spring Valley, Morningside, Edinburgh, Mr. DANIEL MACKENZIE, aged seventy-three years.

— We have also heard of the death, recently, of Mr. FANCOURT, formerly nursery foreman to Messrs. J. Cutbush & Sons, Barnet, and to Messrs. Osborn & Sons, Fulham.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, FEBRUARY 22, 1882.

Table with columns: MONTH AND DAY, BAROMETER, TEMPERATURE OF THE AIR, WIND, RAINFALL. Includes data for Feb. 16-22 and a summary row.

Feb. 16.—A fine bright morning, dull afternoon, but fine. A dull cloudy night.
17.—A dull cloudy morning, fine, bright after. Fine night but cloudy.

ERRATA.—In last week's report for 29.50 mean barometer reading, Feb. 15, read 29.74; and for -0.31 departure from average, Feb. 15, read -0.07.

LONDON: Atmospheric Pressure.—During the week ending February 18, the reading of the barometer at the level of the sea increased from 29.83 inches at the beginning of the week to 30.14 inches by midnight on the 12th, decreased to 30 inches by 3 P.M. on the 13th, increased to 30.29 inches by 3 P.M. on the 14th, decreased to 29.79 inches by 9 A.M. on the 15th, increased to 30.43 inches by 9 A.M. on the 16th, decreased to 30.25 inches by midnight of the same day, increased to 30.36 inches by midnight on the 17th, and was 30.30 inches at the end of the week.

The mean reading for the week at the level of the sea was 30.12 inches, being 0.23 inch lower than last week, and 0.13 inch above the average of the week.

Temperature.—The highest temperature in the shade in the week was 54.5, on the 14th. On the 16th the highest temperature in the day was 48. The mean of the seven high day temperatures was 51.4.

The lowest temperature in the week was 32, on the 16th; on the 14th the lowest temperature was 46. The mean of the seven lowest temperatures was 40.6.

The greatest range of temperature in one day was 16, on the 16th; the smallest was 6.4, on the 17th. The mean of the seven daily ranges was 10.8.

The mean temperatures were on February 12, 47.3; on the 13th, 47; on the 14th, 50.5; on the 15th, 41.8; on the 16th, 41.3; on the 17th, 47.4; on the 18th, 46.2. And these were all above their averages by 8.4, 8.1, 11.7, 3.1, 2.0, 8.7 and 7.4 respectively.

The mean temperature of the air for the week was 45.9, being 8.1 higher than last week, and 7.1 higher than the average of the week.

The highest reading of a thermometer with blackened bulb in vacuo, placed in the full rays of the sun, was 110, on the 12th; the highest on the 13th was 53. The mean of the seven readings was 53.6.

The lowest reading of a minimum thermometer with its bulb placed on grass and fully exposed to the sky was 30, on the 16th. The mean of the seven readings was 36.2.

Rain.—Rain fell on two days to the amount of 0.54 inch, of which 0.38 inch fell on the 15th.

ENGLAND: Temperature.—During the week ending February 18 the highest temperatures were 62 at Sunderland and 59 at Truro. The highest temperature at Brighton was 51.6, at Bradford 53.6, and at Wolverhampton 53.8. The general mean was 55.4.

The lowest temperatures in the week were 29 at Hull and Wolverhampton, and 29.1 at Nottingham. The lowest temperature at Liverpool was 37.3, at Truro 30, and at Bradford 34.9. The general mean was 32.6.

The greatest ranges of temperature in the week were 29 at Sunderland, 25.7 at Nottingham, 25 at Hull. The least ranges were 18.7 at Liverpool and Bradford, and 19.6 at Brighton. The general mean was 22.8.

The mean of the seven high day temperatures was highest at Sunderland, 55.4, at Truro 53.7, at Plymouth and Cambridge 52.1, and was lowest at Wolverhampton 48.4, at Bradford 49, and at Brighton 49.6. The general mean was 51.1.

The mean of the seven low night temperatures was highest at Truro, 42.3, at Liverpool 41.9, and at Plymouth 41.1; and was lowest at Hull, 35.2, at Wolverhampton 36.6, and at Nottingham 38.3. The general mean was 39.7.

The mean daily range was greatest at Sunderland, 15.8, at Hull 15.4, and at Leicester 13; and was lowest at Bradford, 8.6; at Bristol and Liverpool, 8.5. The general mean was 11.4.

The mean temperature for the week was highest at Truro, 47.6, at Sunderland 47.1, and at Plymouth 46.2; and was lowest at Wolverhampton, 42.1, at Hull 42.6, and at Nottingham 44. The general mean was 45.1.

Rain.—The largest falls were 0.98 inch at Truro, 0.03 inch at Leicester, and 0.02 inch at Cambridge. The least falls were 0.03 inch at Sunderland, and 0.06 inch at Leeds, and 0.22 inch at Hull. The general mean was 0.51 inch.

SCOTLAND: Temperature.—During the week ending February 18 the highest temperature was 56, at Glasgow; at Greenock the highest temperature was 50.2. The general mean was 53.6.

The lowest temperature in the week was 28.4, at Aberdeen; at Leith the lowest temperature was 33. The general mean was 31.7.

The mean temperature for the week was highest at Leith, 44.9; and lowest at Aberdeen, 42.1. The general mean was 43.4.

Rain.—The largest falls were 3.35 inch at Greenock, and 2.53 inch at Paisley; the smallest fall was 0.12 inch at Aberdeen. The general average fall was 1.55 inch.

JAMES GLAISHER, F.R.S.

TRADE MEMORANDUM.

We learn from a note to hand from Mr. A. Knight that his present address is Finchfield, Wolverhampton.

The Poultry Yard.

WINTER LAYERS.—The old lady who said she could not understand how it was that always when eggs fetched a good price her hens would not lay, stumbled in a rough way upon a great fact. If hens would lay as well from autumn to spring as they do from spring to autumn, we should have eggs in plenty, but as they do not, of course it is the few who are blessed with winter layers who not only have eggs in a time of scarcity, but get a good return for them.

Obituary.

WE regret to record the death, at Oakley, near Bedford, on the 13th inst., of Mr. ALEXANDER MCKAY, aged seventy-one. Mr. McKay was born at Fochabers, Banff, in 1810, and served his apprenticeship at Gordon Castle.

Enquiries.

He that questioneth much shall learn much.—Bacon.
CHERRY TREES GUMMING.—I have two acres of Cherry trees, which have been planted six years, and I lose annually from twenty to thirty trees from gumming. Can any of your readers suggest the probable cause, or give me a remedy? Market Gardener, Darlington.
DUNCAN STRAWBERY.—Will 'Philomelos' please tell me where I can get the early variety recommended by him under this name? I cannot find it in any catalogue that I possess. W. Clark, Stamford, Darlington.
HOW TO DISSOLVE BONES.—Which is the best method of dissolving bones, about 4 or 5 cwt. at a time? Atherton.
LOGWOOD CHARCOAL.—I send you a sample of refuse from burnt logwood, which I am assured is free from chemicals. Has it any value for horticultural purposes? J. H. Cheshire. Supposing it be what it appears to be, pure charcoal, there is no reason why you should not use it the same as any other charcoal. L1

Answers to Correspondents.

BLOOD MANURE. Constant Reader.—The best way of using blood as a manure is by mixing it with earthy or vegetable matter in the form of a compost, with which you may top-dress your Vines-border. It is of no good in a liquid form.
BOOKS: J. A. Manselton. Thompson's Gardener's Assistant, published by Blackie & Co.
ERRATA.—At p. 223, col. 4, line 8, for "summer-like" read "summerless" and in line 29, for "mats" read "walls."
FUNGUS: J. L. Langford. The plants sent are examples of the true Mushroom—Agaricus campestris. W. G. S.
HILLBORN POWDER: G. Gardner. The powder is prepared from the Christmas Creeper (H. niger), and we cannot account for its failure in the cases you mention. We should not, however, mix the powder with water, but dust the trees with it when they are damp.

NAMES OF FRUITS: 7. *June*. We do not recognise any of them.

NAMES OF PLANTS: 7. *H.* 1. *Eriobotrya japonica*; 2. *Physalis peruviana*; 3. *Polecia oppositifolia*. Send better specimens another time.—*L. N.* 1. *Adiantum tenerum*; 2. *A. decursum*; 3. *A. gracillimum*; 4. *Cheilanthes lutea*; 5. *Polypodium nerolium*; 6. *Selaginella Martensii*—*L. N.* 1. *Zygopetalum crinum*; 2. no flower; 3. *Polypodium ciliare*; 4. *Asplenium viviparum*; 5. *Asplenium Belangeri*; 6. *Polypodium lycopodioides*.—*G. J. H.* Your specimens, very poor ones, arrived smashed. Send better ones, packed in a little damp moss.—*F. H. F.* *Cobbebrum*. 1. *Ficus carica*, 2, 3. *Pyrodium ciliare*; a common cherry 1 flower; sometimes, but very erroneously, called *Lantagha expansa*; 3. probably *Rhododendron lursatum variegatum*—delightfully fragrant.

SAND WASTES OF SOUTH AFRICA. *H. B.* The experiment was suggested in the book you refer to, and, indeed, has been carried out to some extent in various parts of the colony.

STOVE CLIMBERS: *J. O. H.* *Plumbago rosea*, and *Euphorbia laqueiflora*, both of semi-scandent growth, would do well on the back wall of a Cucumber house. The former is not so fast as the latter in a hot state. Neither of them would be found to grow too strongly. *Jasminum Sambac*, fl.-pl., is a good water-flowing climber, with sweet-scented flowers. *J. gracillimum*, of comparatively recent introduction, is also very floriferous and deliciously scented. Either of these should also do well in such a situation, but both of them would want to be watched closely for mealy-bug and white scale. No quarter, however, should be given these insects, especially in a well-managed Cucumber-house, the temperature of which is at all times favourable to their rapid increase. The *Bomarea*s would not be found to do well in such a position; they require more sunlight, less atmospheric moisture, and a somewhat lower temperature, also liberal root-room.

VALU OF ORCHIDS: *J. R. L.* Your best plan would be to show them to some nurseryman. It is quite impossible for us to value your plants.

WILDS. *Juniper*. Arsenic is one of the very best wood destroyers, but of course requires to be used with extreme care. Boil 1 lb. in a gallon of water for half an hour, then add to it 5 gals. of cold water, and pour it on the walks carefully. One dressing a year is sufficient.

Letters relating to ADVERTISEMENTS, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editor.

SEEDS.

LONDON, Feb. 22.—Messrs. John Shaw & Sons, of 37, Mark Lane, E.C., report that there is a good steady consumptive business now passing in farm seeds. The spot supply of Canadian Clover seed being reduced to narrow compass, rather higher prices are now asked for same. Shipments from America continue at a moderate rate. Trefoil is noted £1 to £2 per ton dearer. For Alsike and white full prices are obtainable. More money is asked for perennial Rye-grasses. Imported Italian keeps steady. Santoin is exceedingly scarce. Spring Tares sell freely at full rates. The sale for bird seed is slow.

CORN.

At Mark Lane on Monday the supplies of English Wheat were light, but sales were only practicable at 1s. under Monday's night. Foreign ruled 1s. per quarter lower on good qualities, and 1s. to 2s. on inferior. Flour was dull with a drooping tendency. Fine Barley was firm, secondary and grinding qualities quiet and unchanged. Beans and Peas were unaltered, with a quiet sale. Oats were rather dearer than on the Monday previous.—On Wednesday the business in Wheat was quiet, with a limited extent, leaving quotations unaltered. Flour remained dull. Grinding Barley, whilst quiet, was steady in value. Oats were firm on the spot, but the market was very quiet. Maize remained unchanged in value with very little doing in any position.—Average prices of corn for the week ending February 18.—Wheat, 45s.; Barley, 31s. 10d.; Oats, 21s. 10d. For the corresponding period last year.—Wheat, 41s. 8d.; Barley, 32s. 1d.; Oats, 20s. 7d.

CATTLE.

At Copenhagen Fields on Monday prices for beasts ruled at fully late values to occasionally 2d. dearer. Among the sheep supplies were some good clipped wethers, which sold readily at 6s. 4d. to 6s. 6d., in some cases even rather over. The calf trade was dull, with prices lower. Pigs were a slow sale. (Quotations.—Beasts, 4s. 4d. to 4s. 10d., and 5s. to 6s.; calves, 5s. to 6s. 4d.; sheep, 5s. 6d. to 6s. 4d., and 6s. 10d. to 7s. 6d.; pigs, 4s. to 4s. 10d.—On Thursday trade was dull, and prices only saleable at a decline of 2d. per 8 lb. Prime sheep were steady in value, but other breeds fat. Calves were scarce and dear.

POTATOS.

The Borough and Spitalfields markets reports state that supplies are ample, and trade slow. Quotations.—Kent Regents, 80s. to 100s.; Champions, 60s. to 70s.; Essex Regents, 80s.; Champions, 50s.; Victorias, 100s. to 120s.; Blues, 120s. to 130s. per ton.—The imports into London last week consisted of 127 tons from Roscoff, 130 tons Barleir, 2900 bags Hamburg, and 100 tons from Boulogne.

COALS.

The following are the prices current at market during the week.—Ravensworth West Hartley, 13s. 6d.; Bedside West Hartley, 13s. 6d.; Walls End—Hawthorns, 14s. 3d.; Lamiton, 15s.; Original Hartlepool, 15s. 6d.; Wear, 14s.; South Hetton, 15s. 5d.; Thornley, 14s. 9d.; Tees, 15s. 3d.; Hetton, 15s. 9d.; Hetton Lyons, 14s.

Government Stock.—Consols closed on Monday at 100 to 100½ for delivery, and 100½ to 100½ for the account. Tuesday's figures were respectively 100 to 100½, and 100½ to 100½. The final quotations on Wednesday were, for delivery, 100 to 100, and 100 to 100 for the account. Thursday's closing figures were 100 to 100½ for delivery, and 100½ to 100½ for the account.

Vesuvius and Jean Sisley, 8s. per 100; White Vesuvius, Jennie Dods, Master Christine, Fire King, and President Garnier, 10s. per 100; M. de Lesseps (speardid) 15s. per 100. HENDER AND SONS, Nursery, Plymouth.

SPECIAL OFFER.—Strong Standard CHERRIES and GREEN GAGES; also LIMES, SYCAMORE, Silver BIRCH, ELM, CHESTNUT, and ACACIA, very cheap. T. EVES, Graveyard Nurseries.—Established 1810.

6000 Grape Vines. THE LIVERPOOL HORTICULTURAL COMPANY (JOHN COWAN), Limited, The Vineyard and Nurseries, Garston, near Liverpool, have a splendid stock of VINES grown from eyes this year, suitable for present planting. CATALOGUES free. Trade supplied.

THE EARLIEST WRINKLED PEA.

AMERICAN WONDER.

This valuable new early dwarf Wrinkled Pea was introduced by us last season. It is as early as our Kingleder, which is still the forwardest Round White Pea. The haulm is thickly covered with fine pods, each containing from seven to ten Peas of delicious flavour. Height, 10 to 12 inches.

From Mr. T. TULLOCH, Co. to John Hargreaves, Esq. "American Wonder" Pea proved most satisfactory; it was sown the last week in February, and was fit for use the first week in June—quite as early as 'Kingleder,' sown the first week in January, and it is superior in quality; especially valuable for growing on borders where the trees are a consideration."

From Mr. T. LONGBR, Co. to the Right Hon. Lord O. Fitzgerald. "American Wonder" is exceedingly useful for forcing; only 10 inches high; producing a good crop of fine large Peas, of excellent flavour. Sown in a cold frame, March 20, was ready for use May 10. For forcing it is far superior to 'Little Gem' or 'Tom Thumb.'"

Price, 5s. per Quart; 2s. 6d. per Pint.

THE QUEEN'S SEEDSMEN, { Sutton & Co. } READING, BERKS.

 Mr. Eawkes' New Illustrated Work of Reference on Horticultural Buildings, post-free, 10s. 6d.
Prospectus sent gratis.

KEITH'S PATENT "CHALLENGE" BOILERS, FOR HOT-WATER HEATING.

Can be Heightened or Lowered to suit any requirements. They stand complete in themselves, and require no building work round them, being wholly "water jacketed," and thus entirely free from risk by fire.

These PATENT "CHALLENGE" BOILERS have about ten times the heating surface of the ordinary Saddle Boilers, and are certainly THE BEST, MOST POWERFUL, and MOST ECONOMICAL Hot-water Boilers in use.

See Prospectuses, References, &c.

One of these Boilers has been over a year in use, heating 7500 feet of 4-inch pipe (or nearly 1½ mile of pipe), at the Winter Gardens of Isaac Holden, Esq., Oakworth, Kettleby. This Boiler has only a 30-inch square fire-grate surface, and has 300 square feet of effective heating surface directly over the fire.

JAMES KEITH,
 Gas and Water Engineer,
EDINBURGH and ARBROATH.
 Post Address—EDINBURGH.

THE JOURNAL OF HORTICULTURE, AND HOME FARMER.

ALL GENTLEMEN, AMATEURS, and GARDENERS, who are interested in Grape Culture should read the Special Articles now appearing in the *Journal of Horticulture*, by Mr. Wm. TAYLOR, on the History and Management of the

WONDERFUL VINES AT LONGLEAT.

On October 27, 1881, it was stated: "A similar example of Vine-growing has not been achieved by any cultivator in the Queen dominions." On November 3, 1881, four Muscat Vines, eleven years old, are described as covering nearly 3000 feet of trellis; stems 18 inches in circumference. On December 15, 1881, Mr. Wills wrote: "I was gratified beyond measure: nothing equal to the sight can be witnessed at this period in any part of the kingdom."

All other Gardening Matters are fully and soundly treated in this widely-circulating and popular Journal.

Published Weekly, price 3d; post-free, 3½d.

Mr. W. THOMPSON, Tweed Vineyard, has written the following letter to a gentleman who inquired respecting this Boiler:—

"Galashiels, February 4, 1882.
"The Terminal Saddle Boiler is by FAR the best one we have here, and we have had all sorts. It does its work well, and with less fuel than most Boilers. It is the most economical and efficient Boiler we have, and has not cost sixpence since we fixed it some eight years ago."

Illustrated Prospectus Post-free.

FOREMAN.—Mr. E. GILMAN, Ingestre Gardens, Stafford, can with confidence recommend his Foreman to any Nobleman or Gentleman requiring the services of a thorough practical and trustworthy man. He has a thorough knowledge of the profession in all its branches, and has first-class testimonials from his previous employers.

FOREMAN PROPAGATOR or GROWER.—Well up in all the requirements of a Market Nursery; able also to combine Growth of Fruits under Glass. Good references.—G. H. BROOKER, London Road, East Grinstead.

FOREMAN and PROPAGATOR, or PROPAGATOR.—Has had experience in and about Softwood Plant and Greenhouse Plants, and Cut Flower. Good references.—T. D., Hugh Low & Co., Clapton, London, E.

NURSERY FOREMAN, SALESMAN, and MANAGER.—Experienced in the Culture of Fruits and general outdoor stock. Good references.—W. T. C., Bridgefield Dairy, Warple Way, York Road, Wandsworth, S.W.

JOURNEYMAN, in a good establishment.—Age 22; first-class references.—S. B., Pine-apple Nursery, Maiden Lane, London, N.W.

JOURNEYMAN, under a good Gardener.—Age 25; five years' experience. Good character.—G. FLOOD, Lavestoke Gardens, Micheldever, Hants.

JOURNEYMAN, or under a Foreman, in the Houses.—Age 18; bothy preferred. Good character.—A. E., 32, Prospect Road, Well's Road, Sydenham, S.E.

JOURNEYMAN, in the Houses, where he could gain some knowledge of Outdoor Work.—Age 21. Two years' good character.—W. POTTLE, The Gardens, Stoke Court, Slough, Berks.

JOURNEYMAN, in the Houses, in a good establishment.—Age 20; three years' good character from present place.—W. M. SPINK, Easton Park Gardens, Wickham Market, Suffolk.

JOURNEYMAN, in a good establishment, where he would be principally employed in the Fruits and in the Vine; nine years' experience in the general routine of Gardening. To live in bothy preferred. References from the present situation.—HENRY HINSLEY, Gellestone Hall Lodge, near Beccles, Norfolk.

PROPAGATOR, or SECOND, in a Gentleman's place.—Age 23, single; eight years' experience. Good reference.—E. WARDEN, 2, Percival's Cottages, Pincoot Road, Merton, Surrey.

PROPAGATOR (ASSISTANT), in a good establishment.—Age 21; four years' good character as above. Can be well recommended by present and previous employers.—A. BROOKER, London Road, East Grinstead, Sussex.

PROPAGATOR (ASSISTANT).—Age 21; thorough experience in Propagating Roses, Clematis, Apple, Rhododendrons, &c. Eight years' excellent character. Apply, stating wages, to E. W., King's Acre Nurseries, Hereford.

PROPAGATOR and GROWER of Market Plants and Cut Flowers.—Young, single; well acquainted with the business. First-rate character as to abilities and personal habits.—S. B., Toll Gate, Lindfield, Sussex.

PROPAGATOR and GROWER, in London or Provincial Nursery.—Best references. Well up in Propagation and Cultivation of Stove and Greenhouse Plants.—H. B., 29, Church Road Terrace, Lower Tottenham, London.

PROPAGATOR (UNDER), or ASSISTANT GROWER.—Near London preferred. Six years' experience. Assisted to Market Nursery work. Good references.—K. D., Mrs. H. Bissett, Cemetery Road, East Grinstead, Sussex.

To Gentlemen.—MANAGER.—Age 37; to Grow for Market Grapes, Peaches, Cucumbers, Tomatos, Tea Roses, and Choice Plants for Cut Flower Trade. Thoroughly experienced in Market Work.—G. B. H. J. J. J.

MANAGER.—ADVERTISER wishes engagement in a Nursery or Glass Plant or Glass House. Good references.—J. OSBORNE, Kay's Nursery, North Finchley, N.W.

IMPROVER.—Age 19; seven years' character. No objection to pay a small Premium.—JOHN CLARKE, The Gardens, Beaumont Park, Leicestershire.

IMPROVER.—Age 19; five years' experience. Good character. Willing to pay a Premium.—F. PAICE, Priet, Alton, Hants.

IMPROVER, in a first-class establishment, where he can learn thoroughly.—Age 19; Premium £5.—C. C., The Borough, Old Tisbury, Hants.

IMPROVER, in the Gardens of a Nobleman or Gentleman.—Age 19; Lancashire preferred. HENRY KERR, 3, Freckleton Street, Wigan Lane, Wigan.

IMPROVER (PROPAGATOR, or ASSISTANT).—Age 17; used to Hard and Soft Wood. Three years' good character.—A. D., 6, Model Cottages, Denmark Road, Wimbledon, Surrey.

IMPROVER, under a Foreman.—Age 19; understands Potting, Tying, and Watering. Bothy preferred. Excellent character.—W. C., Vicarage, Finwell, Haverkirk.

IMPROVER.—ADVERTISER (age 21) desires a situation in a Nobleman's or Gentleman's establishment where he would have an opportunity of improving himself, especially in Stove and Greenhouse Plants. Total abstinence, and well recommended.—W. F. PRINCE, Green-gate, The Vineyard, West Lynn, Norfolk.

TO NURSEMYN and SEEDSMEN.—Situation wanted by a young man, of over 20 years' experience, as GENERAL ASSISTANT in the Shop and Office. Would be willing to go anywhere, and make himself generally useful. Unexceptional testimonials for competency, honesty, &c. Terms very moderate.—G. MESSRS. A. GOODMAN & SON, Nurserymen and Seedsmen, Londonderry.

TO HEAD GARDENERS.—Mr. H. GILBERT is desirous of placing his son (age 22) in a Nobleman's or Gentleman's Garden where Early and Late Fruit Forcing are carried on extensively. Has had eight years' experience in different departments of Gardening. Good character.—The Gardens, Southwick Park, Fareham, Hants.

SHOP MAN (HEAD).—Married; total abstinence. Thoroughly experienced in every branch of Retail Trade. Has had entire charge for the past ten years. Efficient Correspondent and Post-office Order Writer. No objection to travel.—G., 43, Landor Road, Clapham, S.W.

SALESMAN, in a Florist's Shop.—Well up in the nomenclature of Plants, Buying, Pricing, Selling, Furnishing, giving Estimates, &c. Thirteen years' experience with leading London firms. First-class testimonials as to ability, &c.—Apply, in letter, to G. WOOTEN, 9, Park Terrace, Baker Street, W.

By a thorough knowledge of the natural laws, which govern the operations of digestion and nutrition, and by a careful application of the fine and purest Food of the selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately-flavoured beverage which may save us many heavy doctor's bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maldies afloat around us ready to attack and finally overthrow the weakest of us. We may escape many a fatal illness by keeping ourselves well fortified with pure and healthful food and drink prepared in this way.—*Crested Star Gazette.*

MADE simply with boiling water or milk. Sold only in packets, labelled, JAMES EPPS and CO., LIME PATH CHEMISTS, London.

Makers of Epps's Chocolate Essance for Afternoon use. A Comfortable Night's Refreshing Sleep is insured by DR. LOCKOCK'S PULMONIC WAFERS.—Mr. JOHN PEARSON, 67, York Street, Whitechapel, writes:—"I had no sleep for five weeks till I tried Dr. Lockock's Wafers, and I have had such relief to the cough that I could not have believed." Asthma, Consumption, Colds, Gout, Bronchitis, Rheumatism, and all nervous complaints, are instantly relieved and rapidly cured by Dr. Lockock's Wafers, which taste pleasantly. Of all Druggists, at 1s. 1/2d. and 2s. 9d. per box.

HOLLOWAY'S PILLS.—Weak Stomach.—The wisest cannot enumerate one quarter of the distressing symptoms arising from imperfect or disordered digestion, all of which can be relieved by these admirable Pills. They remove canky taste from the mouth, flatulency and indigestion. Holloway's Pills rouse the stomach, liver, and every other organ, thereby bringing digestion to that healthy tone which fully enables it to convert the food into nourishment for the support of our bodies. Hence these Pills are the surest strengthener—and the safest restoratives in nervousness, wasting, and chronic debility. Holloway's Pills are equally adapted for impaired appetite, eructations, and a multitude of other disagreeable symptoms which render the lives of thousands miserable indeed. These Pills are approved by all classes.

GREEN'S PATENT "SILENS MESSOR" & "MONARCH" NOISELESS LAWN-MOWING, ROLLING and COLLECTING MACHINES for 1882.

THE WINNERS OF EVERY PRIZE IN ALL CASES OF COMPETITION.

Patronised by Her Most Gracious Majesty the Queen on many occasions,
His Royal Highness the Prince of Wales,
the King of the Belgians,

the late Emperor of the French, the Emperor of Russia,
and most of the Nobility, Clergy, and Gentry
of the United Kingdom.

Upwards of 105,000 of these Machines have been Sold since they were first introduced in the year 1853,
And Thousands of unsolicited Testimonials have been received testifying to their superiority over all others.

They have been submitted to numerous practical tests in Public Competition, and in all cases have carried off every Prize that has been given.

The following are their advantages over all others:—

- 1st. Simplicity of all construction—every part being easily accessible.
- 2d. They are worked with much greater ease than any other.
- 3d. They are the least liable to get out of order.
- 4th. They make little or no noise in working.
- 5th. They will cut either short or long Grass, wet or dry.

Single-handed Lawn Mower.

This can be worked by One Man on an even Lawn.	
To cut 18 inches	7 10 0
By a Man and Boy.	
To cut 20 inches	8 0 0
By a Man and Boy.	
*To cut 22 inches. By Two Men ...	8 10 0
*To cut 24 inches. By Two Men ...	9 0 0
* If made stronger, suitable for Donkey, 30s. extra.	

Prices of Donkey, Pony, and Horse Machines, including Patent Self or Side Delivery Box, with Cross-stay complete, suitable for attaching to Ordinary Chaise Traces or Gig Harness:—

DONKEY and PONY MACHINES.

To cut 26 inches	£14 0 0
To cut 28 inches	15 0 0
To cut 30 inches	18 0 0
Leather Boots for Donkey	1 0 0
Leather Boots for Pony	1 4 0

HORSE MACHINES.

To cut 30 inches	£22 0 0
To cut 36 inches	26 0 0
To cut 42 inches	30 0 0
To cut 48 inches	34 0 0
Leather Boots for Horse	1 9 0

The 26 and 28 inches can easily be worked by a Donkey, the 30 inches by a Pony, and the larger sizes by a Horse; and as the Machines make little noise in working, the most spirited animal can be employed without fear of its running away, or in any way damaging the Machine.

Delivered, Carriage Free, at all the principal Railway Stations and Shipping Ports in England, Scotland, and Ireland.

No Lawn Mower Manufacturer keeps so large a stock of Mowers as is to be found at our London Establishment, 54 and 55, Blackfriars Road, where purchasers can select out of several hundred Machines, of Hand, Pony, and Horse Power, and have their Orders executed the same day they are received.

The above Machines are Warranted to give entire Satisfaction, otherwise they may be returned AT ONCE, free of cost to the Purchaser.

N.B.—Those who have Lawn Mowers which require repairing should send them to either our Leeds or London Establishment, where they will have prompt attention as an Efficient Staff of Workmen is kept at both places.

Garden Seats and Chairs, and Horticultural Implements of every description, Wire Netting, &c., &c. Price Lists on application.

GREEN'S PATENT ROLLERS

For Lawns, Drives, Bowling Greens, Cricket Fields and Gravel Paths.

SUITABLE FOR HAND OR HORSE POWER.

These Rollers are made in two parts, and are free in revolving on the axis, which affords greater facility for turning. The outer edges are rounded off, or turned inwards, so that the unsightly marks which other Rollers leave are avoided by users.

J. H. LEY,
ROYAL NURSERY, WEST CROYDON.

Orchids a Speciality.

The stock at the Clapton Nursery is by far the largest hitherto seen in Europe, and is of such magnitude that, without seeing it, it is not easy to form an adequate conception of its unprecedented extent.

HUGH LOW & CO.
 very cordially and respectfully solicit an inspection by all lovers of this interesting and beautiful class of plants, whether purchasers or not.

CLAPTON NURSERY, LONDON, E.

A SEED LIST

ILLUSTRATED
 and as full as can be desired of useful and reliable information on Garden and Flower Seeds, yet without any unnecessary costliness, post-free on application. Such a catalogue as this is claimed to be of most necessary conduce to economy, both as regards purchaser and vendor.
 In addition to the well known and trusty favourites in Seeds, the

BEST NOVELTIES
 are included, but unproved and excessively expensive kinds are omitted.

Every endeavour is made to supply Seeds of the *Finest Quality and of the Best Varieties at a Moderate Price*, to attain which desirable object neither trouble nor expense are spared in the procuring and proving of the Seeds.

THE GUINEA COLLECTION

(Carriage free) for the Amateur's Garden, has been much approved, and contains a most valuable and useful assortment of Vegetable Seeds.
 All enquiries are gladly and promptly attended to.

"The one pound of WHITE ELEPHANT was turned out very fine. I have lifted 220 lb. from it."

DANIELS BROS.,

ROYAL NORFOLK SEED ESTABLISHMENT, NORWICH.

MASDEVALLIA ROEZLII

(ROEB. F.),

THE BLACK CHIMERA MASDEVALLIA.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., by order of Mr. F. SANDER, on THURSDAY, March 9, at half-past 12 o'clock precisely, the above splendid new MASDEVALLIA. It belongs to the Chimera section, and received a First-class Certificate at South Kensington. Professor Reichenbach says this fine Masdevallia is a Chimeroid species, of a wonderful dark blackish-india-purple, with still darker or warts, and very few short light purple hairs on the edges of the sepals. Flowers measure between tail ends 16 inches. At the same time will be sold importations of many fine DENDROBES, including D. SUAVISSIMUM, D. DEVONIANUM, D. WARDIANUM, D. THYRSIFLORUM, D. FALCONERI, D. PARISHI, D. SANGUINOLENTUM, D. RHODOPTERYGIUM, and many others.

On view morning of Sale, and Catalogues had.

AUCTION ROOMS AND OFFICES, 38, KING STREET, COVENT GARDEN, LONDON, W.C.

B. S. WILLIAMS

Begs to invite Orchid Growers and all who may be interested in this popular class of Plants to an Inspection of his Large Collection of

ORCHIDS.

There are now in bloom many hundreds of ODONTOGLOSSUMS and other Cool ORCHIDS, including ODONTOGLOSSUM ALEXANDRE, many fine varieties; also the lovely O. PESCATOREI, in large plants; the rare O. PARDINUM, with its golden-yellow flowers; also the rare O. HORSMANII, O. POLYXANTHUM, very distinct; O. TRIUMPHANS, O. CIRROSUM, O. VENILLARIUM, O. ROEZZII ALBUM, O. ROSSI MAJUS, and many other kinds, such as ADA AURANTIACA in specimens, with many spikes of its orange-scarlet flowers; SOPHRONITES GRANDIFLORA, CELOGYNE CRISTATA, and the rare variety, LEMONIANA, in large specimens; also a great variety of LYCASTE SKINNERI, in large well-grown Plants.

The SHOW HOUSES are also gay with PRIMULAS and CYCLAMEN, AMARYLLIS in great variety, coming into bloom; also fine specimens of IMATOPHYLLUM MINIATUM SPLENDENS, &c., in full beauty.

VICTORIA AND PARADISE NURSERIES,
UPPER HOLLOWAY, LONDON, N.

NISBET'S VICTORIA TOMATO

This is a seedling from Vick's "Criterion," and for cultivating under glass or in the open air there is no Tomato can approach it for fruitfulness. The plant requires no stopping, as it keeps growing and fruiting in the greatest abundance. The fruit is pyriform, and grows in bunches, each bunch containing from eight to twenty fruit, which are the size and colour of a Victoria Plum. It contains but few seeds, and for flavour is unsurpassed.

Per Packet, 1s.

By cultivating the Victoria Tomato there is no difficulty in obtaining a dish of Tomatoes ALL THE YEAR ROUND. The plant requires plenty of room and a rich loamy soil, with liberal applications of liquid manure. There is no fear of its producing a quantity of wood without fruit, as the bunches of fruit show at every joint; it needs no stopping, as it keeps growing and fruiting in the greatest abundance, and either for cultivating under glass, or in the open air, it surpasses all others for fruitfulness.

To grow it in the greatest perfection a few of the many bunches should be removed and the fruit thinned out a little. This will produce fine, large, handsome fruit.

"The Original Plant is growing, under glass, at Aswarby, covering a space 15 feet by 6 feet, and at the present time is carrying a crop of 600 bunches of fruit, as many more having been gathered from it during the summer.

"August 30, 1879.

"RICHARD NISBET, Gardener, Aswarby Park."

Independent Slow Combustion Boiler for Small Greenhouses.

TO HEAT BY HOT WATER; REQUIRING NO BACKWORK.

Specially adapted for small greenhouses; for quick heating or slow combustion. Quite portable, and will heat properly for twelve hours. Made with strong wrought-iron cylinder set in a cast-iron base, with fire-bars and sliding door. Only one-tenth the cost of heating by gas, and much more effective. Fitted with two 2-in. cast sockets, door for feeding, and socket for smoke-flee.

Cash Prices—Carriage paid.

of Boiler complete, as shown in illustration, but exclusive of piping is—

Size.	Total Height.	Diameter.	To heat 4-in. Piping.	Price.
1	27 in.	16 in.	45 ft.	£3 10 0
2	30 in.	16 in.	60 ft.	4 0 0
3	33 in.	16 in.	80 ft.	4 10 0
4	36 in.	16 in.	100 ft.	5 0 0

Plain Saddle Boiler.

Plain Saddle Boilers are generally used for heating from 100 feet to 300 feet of 4-in. piping; and above that quantity it is more economical to use our Check-end Boiler, as one of these, 3 feet long, will heat double the quantity of piping a 3-foot Plain Saddle will.

Size of Sockets.	Size of Boiler inside arch.			Heating Power for 4-in. Piping.	Prices on application.
	Length.	Width.	Height.		
Fitted with 2 Sockets.	18 in.	12 in.	10 in.	100 ft.	
	21 in.	12 in.	10 in.	125 ft.

	36 in.	16 in.	16 in.	300 ft.	

The Perfect Throttle Valve.

2-in. 105. 6d.
3-in. 125. 6d.
4-in. 155. 6d.

The whole of the working parts of these valves can be removed without disturbing or cutting the pipes.

Screw Valves. Tight under any Pressure.

2-in. 135. 6d.
3-in. 205. 6d.
4-in. 275. 6d.

The Phoenix Slow Combustion Boiler.

We claim for our Phoenix Upright Boiler the following good qualities, viz.—It is made of the best materials; has no parts that are liable to failure; is provided with a flue that cannot be choked with fuel; will heat effectively the quantity of pipes stated with the smallest amount of fuel; can be easily regulated; and will hold fuel sufficient for keeping up the proper heat twelve hours; requires no break-work, and takes up the smallest space of any boiler of its power.

Sockets can be placed in any position.
Cash Prices—Carriage paid.

SEEDSMEN

By Special
To H.R.H the

Warrant
Prince of Wales.

Carters

To Her
Majesty

SEEDSMEN

Gracious
The Queen.

237 and 238, HIGH HOLBORN, LONDON, W.C.

WEBBS' SEEDS OF BEAUTIFUL FLOWERS.

WEBBS' DOUBLE GERMAN STOCKS.

From W. WOOD, Esq.—“My Stocks last season from your seed were splendid.”
Mixed Colours.
1s. per Packet.

WEBBS' NEW VICTORIA ASTER.

From Mr. THOMAS SELWYN, Gr. to Miss Herford.—“The Asters produced the finest blooms I have ever seen.”
Mixed Colours.
1s. per Packet.

WEBBS' ROSE-FLOWERED BALSAM.

From Mr. R. H. FIELD, Crutshury.—“The Balsam is a perfection.”
Mixed Colours.
1s. per Packet.

WEBBS' SHOW PANSY.

From Mr. F. HEATH, Gr. to Lt. Bishop of Lichfield.—“Your Show Pansies are excellent.”
Per Packet,
1s. 6d. and 2s. 6d.

WEBBS' BRILLIANT PETUNIA.

From Mr. S. MORTON, Oulton.—“Your brilliant Petunia is really beautiful.”
Per Packet,
1s. 6d. and 2s. 6d.

WEBBS' DEFIANCE AURICULA.

From Mr. R. P. INALL, Cottenham Park Villa.—“Your Defiance Auricula is a splendid variety, far surpassing the old kind.”
Per Packet,
1s. and 2s. 6d.

WEBBS' EXQUISITE PRIMULA.

From Mr. W. L. HUTTON, Esq., Fairfield Cottage.—“The seed of your Exquisite Primula was very good.”
Per Packet,
2s. 6d. and 6s.

WEBBS' SUPERB CALCEOLARIA.

From Mr. HATHAWAY Gr. to Capt. J. Beavan.—“The Calceolaria was a magnificent strain of almost every shade of colour.”
Per Packet
1s. 6d. and 2s. 6d.

WEBBS' SUPERB CINERARIA.

From Mr. JAS. STOCKER, Gr. to W. E. Wiley, Esq.—“I had a grand display of your Superb Cineraria.”
Per Packet,
1s. 6d. and 2s. 6d.

THE QUEEN'S SEEDSMEN.
WORDSLEY, STOURBRIDGE.

THE BEST GARDEN LAWNS, CROQUET LAWNS, LAWN TENNIS GROUNDS, CRICKET GROUNDS,
Are obtained by Sowing

SUTTONS' PRIZE MIXTURES OF GRASSES and CLOVERS
Specially prepared for the above purposes

SPECIAL GOLD MEDAL, Melbourne, 1880-81.
PRIZE MEDAL, Paris, 1878.

“Melbourne, October 23, 1880.”
“Sir,—By direction of the Commissioners for the Melbourne International Exhibition I have to request that you will be so good as to convey their best thanks to Messrs. Sutton & Sons, of Reading, for their valuable Lawn Grass Seeds planted in the grounds of the Exhibition during the late winter. The seeds have germinated freely, and the lawns are now in splendid condition. Messrs. Sutton & Sons may accept my assurance that the introduction of their Lawn Grass Seeds into this country has been attended with very great success—I have the honour to be, Sir, your most obedient servant,
(Signed) GEORGE C. LEVEY, Secretary,
To the CHIEF CLERK, Melbourne International Exhibition Offices, London.”

The three splendid Lawns at the Paris Exhibition, 1878 produced from our seeds, were awarded a Prize Medal, and thus referred to by “L'Echo Agricole”:
“The Lawns shown by Messrs. Suttons' Agent are at least equal in beauty, vigour, and luxuriance to those shown by any other Exhibitor. They are of extraordinary beauty and evenness, and form throughout one charming velvety carpet.”

From T. F. GRAHAM, Esq., Abingdon.
“About two years ago you supplied me with some Lawn Grasses and Clovers which have made some of the best Lawns I have ever seen, and I now want to add to them.”
From Mr. C. W. ALCOCK, Secretary, Surrey County Cricket Club, Kingston Oval.
“The Committee desire me to say that they have every reason to be satisfied with the Grass Seeds you have supplied for this ground during the last few years.”

SATURDAY, MARCH 4, 1882.

PLANTS OF MYTHOLOGY.

THE welcome arrival of the early flowers recalls myths and fancies connected with them which have been passed on through ages of time, and which the world could ill afford to lose, idle though they be.

“Sweet was the fancy of these antique ages
That put a heart in every stirring leaf,
Writing deep moral upon Nature's pages,
Turning sweet flowers into deathless sages
To calm our joy and sanctify our grief.”

The great inventors of pleasing fancies and stories about plants and flowers were the many-minded Greeks and the religious Romans: the people who invented “Dodonian Jove” and forty other gods must have been religious. Science has deprived us of some of the materials of the classic ages; it has driven the wood nymphs from their trees, and the dryads from their brooks and fountains, and the illusions of the “antique world” could hardly be revived by a modern poet as by Milton, when he wrote—

“By dimpled brook and fountain brim,
The wood nymphs deckt with Daisies trim,
Their merry wakes and pastimes keep.”

The world has grown too “knowing” for actual belief in the fancies of old times, but we can still feel pleasure in repeating them. There is a pleasure, too, in tracing the meaning of the many legends relating to the vegetable kingdom.

The “everlasting hate” entertained between the Vine and Ivy is easily explained, for the first-named trailer grows in the sun, and the Ivy affects shade, and twines upon old walls and ruins. Mrs. Hemans says of it—

“Thy home, wild plant, is where each sound
Of revelly hail long been o'er;
Where sun's full notes once pealed around,
But now are heard no more.”

It is as easy to explain Juno's dislike of the Myrtle, since Venus was adorned with that plant when Paris awarded her the prize of beauty. And for the same reason, although the Myrtle was a favourite flower of the Romans, worn by their heroes as a mark of victory, and by bridegrooms on the bridal day, they very delicately excluded it from the festival of Minerva, to avoid reminding the goddess of her defeat. It must have been the same sentiment of jealousy which rendered the Lily and the Lotus, flowers of Juno, obnoxious to Venus. Her flowers were the Rose, Anemone, Cypress, Apple, Poppy, Myrtle, and Violet. Anemones sprung from the tears she shed over the body of Adonis, and the blood of that handsome youth mingling with them, caused the instant appearance of the Flos Adonis.

“By this the boy that by her side lay killed
Has melted like a vapour from her sight;
And in his blood, that on the ground lay spilled,
A purple flower sprung up, chequered with white.”

Most unfortunately for our world purple flowers now spring from seed, and sometimes slowly; weeds alone grow by magic.

It is not at first sight obvious how the Rose—a flower dedicated to beauty, love, and wine, or, in other words, to Venus—should have become the emblem of silence; but the legend runs that Venus gave a Rose one day to Cupid, who

presented it to Harpocrates, the god of Silence, begging him at the same time to conceal such little slips and fallings among the gods as Cupid might occasion. So Roses were worn at festivals in sign that the confidence of the festive hours, which warm the heart and open the bosom's hiding-places, should not be abused. The sculptured Rose over the portals of ancient banquetting halls conveyed the same hint, and occasioned the phrase "sub rosa."

Notwithstanding the numerous flowers awaiting notice it is not easy parting with the Rose. Sappho's verses are irresistible:—

"Sweetest child of weeping morning;
Gen, the west of earth adorning;
Eye of flow'rets, gulf of lawns,
Bud of beauty, nursed by dawns:
Soft's the soul of love it breathes,
Cyprus's brow with magic wreathes,
And to the Zephyr's warm caresses
Diffuses all its verdant tresses:
Till, glowing with the wanton's play,
It blushes a diviner ray."

Other poets have other theories on the colour of the Rose, as, for example, that the white Rose became red when Venus stepped on a thorn—

"And while the wound with crimson flows,
The snowy flow'ret feels her blood and blushes!"

Or, according to Herrick—

"As Cupid danced among
The gods, he down the nectar flung,
Which, on the white Rose being shed,
Made it for ever after red."

The Violet—favourite of the Athenians and of Napoleon—emblem of Athens, engraved on tablets erected throughout the city, is a flower of romantic origin, according to the poets, though they have given different versions of its creation. The trees were assigned, by poetic fancy, to various celebrities. The towering Ash was the tree of Mars, the Oak of Jove, the Pine of Pan, who turned a nymph beloved by him into a tree of that description, and whom we may hold responsible for the panic dread sometimes experienced in the depths of Pine woods when the wind moans and darkness closes around a dubious road. As a rule, the climbing plants avoid the various species of Pine, though the Mistletoe grows on some of them, finding better entertainment, as a parasite, on the branches than climbers could experience when rooted in a mass of Fir leaves covering an impenetrable layer of shallow surface roots.

The origin of the Fir belongs to mythology, for Atys was metamorphosed into a tree, which was the first Fir tree. Its evergreen habit was due to Zeus, who found Cybele beneath the tree, mourning for Atys, and immediately ordained that the Fir should remain evergreen. Thus it happened that Pines and Firs were dedicated to Cybele, as they also were to Neptune, because the first boats were constructed of their timber.

The Laurel is another tree due to metamorphosis and dedicated to Apollo, who pursued the virgin Daphne with felonious intent, and was just on the point of overtaking her when Divine interposition changed her to a Laurel. The exigencies of poetry have led to several botanical errors, and much confusion has arisen as to the Bay tree and the Laurel.

"The Laurel, meed of mighty conquerors and poets
sage,"

sings an inaccurate bard, meaning, no doubt, the Bay. Cæsar wore a "Laurel crown by special decree of the Senate, and he highly appreciated the opportunity of concealing his baldness, a defect which was reckoned a deformity among his countrymen and among the Jews, whose hair, as a rule, is singularly adherent. It is stated on good authority, however, that Cæsar's crown was not formed of

Laurel or Bay, but of *Ruscus hypoglossum*, a species of Butcher's Broom, called Alexandrian Laurel, though native to Italy.

The most useful tree of the Mediterranean countries owed its miraculous origin to the dispute between Neptune and Minerva at the naming of Athens. The gods decided that the presentation of the best gift to mankind should confer on the giver the honour of naming the city. Neptune at once produced the horse, which sprang from the shore on his striking it with his trident; and the horse is certainly a useful gift, but it typifies war, and Minerva triumphed when she called into being the symbol of peace. Spenser thus describes the process:—

"She smote upon the ground, the which straight forth
did yield
A fruitful Olive tree with berries spread."

It is reported as true history that the Olive has been grown in Syria throughout the historic period, and that it was unknown in Italy at the building of Rome. Probably some Roman traveller brought it from Asia, and others afterwards carried it to Spain, Gaul, and England, where it ripens on a wall in Devonshire. But this prosaic statement warns us to desist from carrying our subject further at present. *H. E.*

New Garden Plants.

OCHINA MULTIFLORA.

THIS remarkable stove shrub is now in bloom at the Holloway Nurseries. The flowers are yellow, with five roundish petals and numerous stamens, whose anthers open bypoceat at the top. So far there is nothing very remarkable about the plant, but as the petals fall off the thalamus of the flower—that part from which all the other parts spring, and which is really the top of the flower-stalk—begins to swell, and finally assumes the form of a large, 5-sided, 5-angled cushion the size of a large Cherry or small Plum, bearing on each of the five angles a carpel or seed-vessel, becoming black when ripe. The sepals, unlike the petals, do not fall off, but remain and increase in size. So far this might be deemed a botanical curiosity only, but the brilliant crimson colour assumed by the thalamus and the persistent sepals give it a distinguished place among ornamental stove plants. It seems probable that the object of this brilliant coloration may be to attract birds, by whose agency the seed may be dispersed. The botanist will recognise in the swollen, brilliantly coloured thalamus a precise correspondence with the Strawberry, the edible portion of which is the thalamus, the pips being the seed-vessels, in this case arranged spirally, and not in a ring, as in the *Ochna*.

TACSONIA PARRIFL. Mast. (See ante, p. 218.)

SINCE writing our previous notice of this plant we have had the opportunity of seeing further material in the hands of Mr. R. S. Williams, who has had the plant since 1879. What we have seen at Mr. Williams' serves to confirm all we have said as to the distinctness and remarkable character of this species. If the flowers in cultivation present the same colour as they do in a wild state—salmon-orange—we may say that up to this time nothing like it has been seen among cultivated Passion-flowers.

POLYSTACHYA DINANTHA, n. sp.*

THIS is a curious species, in the way of *Polystachya rigida* Rehb. f. It is much taller, and comes near in growth and nature of leaves to *Polystachya ensifolia*, Lindl. The raceme at hand is simple and the flowers are equal to those to *Polystachya bracteosa*, Lindl., ochre-coloured, with a quite distinct lip, whose side lobes are purple and the disk dark yellow. There is a half-sphere callus of orange colour in the disk. It was imported by Mr. T. Christy, of Malvern House, Sydenham, from the West Coast of Africa. *H. G. Rehb. f.*

* *Polystachya dinantha*, n. sp.—Caule teretissimo diphylo; foliis linearibus acutis, reticulato flavogrunato, venis tenuis arcuatis; rachis velutina laxillifera; bracteis triangulis ovario puberulis; brevissimis. Fl. roseo; "inverso;" sepalis lateribus in angulum obtusum maximum extensis; triacutis acumineatis puberulis; sepalis imbricatis linearibus triangulis; tepalis linearibus falcatis acutis; labellis a basi lata cuneato dilatato laciniis lateribus medianis quadratis, lacina media triangula apiculata, tertia superiore pilulosa (non puberula); callo transverso semiquadrato in disco superiore.—Ex Afr. occid. trop. insup. or col. T. Christy. *H. G. Rehb. f.*

DAVALLIA BULLATA.

I CONSIDER this Fern to be one of the most valuable kinds grown among the whole family of Ferns. For durability in a cut state it has scarcely an equal during the summer and autumn months. Small plants of it are valuable in many ways, especially for furnishing, whilst as a specimen for exhibition it is most distinct, and always admired. Our large specimen is just pushing up its first crop of fronds, which in a few weeks will be a complete thicket of a beautiful pale green colour. It has just been top-dressed with a little fresh peat, sphagnum moss, and silver-sand, any straggling rhizomes being pegged on to the fresh soil.

We shall now remove it into a Peach-house where the fruit is set. There it will stand till the house is thrown open after the fruit is gathered. In this house it grows far better than under stove treatment. It was not shaded during the hottest weather of last summer beyond what the Peach trees afforded it; previously we have shaded with tiffany, but find it does better without any such attention. A close confined atmosphere does not suit it; the dense growth it makes will damp off under such conditions.

When the Peach-house becomes too cold for it we remove it again to a temperate-house, where it stands till growth commences again in the spring. When the fronds begin to decay in the late autumn (being a deciduous kind) we withhold water somewhat gradually, removing all the fronds a few at a time. It is a variety that is very easily increased by division of its rhizomes. I have often wondered why this useful Fern is not more grown than it is. It ought to be in every collection. *James Hudson.*

RHODODENDRONS.

THE Editor writes to me:—"Is there any marked difference in the seedlings of Rhododendrons?" In venturing to give an answer to this question, so far as my observation and experience among Himalayan Rhododendrons permits, I will for the present confine the word "seedlings" to plants grown from seed imported from their native places, that is to say, plants of the first generation, and my answer must be in the negative. I believe that a packet of seed, gathered from the same species and in the same locality, will yield in Europe seedlings, not of course, absolutely uniform, but certainly showing no marked difference. This result, although often questioned, was surely to be expected, seeing that Himalayan Rhododendrons are mostly social plants, and must commend itself to the experience of our old-fashioned R. ponticum, which, when kept apart from other species and hybrids, continues very true for many generations. Certainly, for the first generation, the seedlings of Himalayan Rhododendrons are often produced in great numbers, almost absolutely alike. Sometimes this uniformity descends to later generations, and sometimes even to hybrids. Thus Mr. J. Sheppard has raised about 150 hybrids between R. Edgeworthii and R. formosum, most of which have bloomed, and he can see no difference whatever in any of them. I must not, however, at present go so far afield, but confine myself to the assertion that carefully collected native seed will, when grown in this country, faithfully reproduce the parent type.

I may see, perhaps, to have unduly laboured this highly probable statement. Nevertheless, the Editor's question is a very important one, even in my limited sense, and is not to be disposed of quite easily. For how comes it that in European collections there prevails such a variety of type with plants of the first generation as fairly to puzzle a connoisseur? Specialists are often justly accused of magnifying unimportant distinctions, but I hope to avoid this charge on the evidence about to be adduced. Take, for instance, R. fulgens, which has been derived exclusively from Sikkim or close by, figured very finely in Sir J. Hooker's magnificent work from his own drawing taken on the native spot. After awhile the seed transmitted by him to Kew produced plants and blossom, and a plate of that blossom appeared in the *Bot. Mag.*, prepared by the very best flower artist. Now, I defy any one to remark a most striking difference between the two portraits, and this not in colour, but in character. The *Botanical Magazine* indeed mentions one difference, and the section of the ovary suggests another; but I have seen in living plants of the first generation quite enough to make

me believe both portraits correct, and each type distinct. Again, the late Mr. Gorrie was one of the first to grow Sikkim Rhododendrons, and in 1854 he was reporting on them to Sir J. Hooker, who published his reports. In these reports he noticed that he had apparently several forms of *R. fulgens*. Mr. Gorrie continued to grow Rhododendrons, and shortly before his death in 1880 he read a paper to the Edinburgh Botanical Society, in which he gave so extraordinary an account of a so-called *R. fulgens* that I thought it desirable to ask leave to inspect his plants. Among them I found one form of *R. fulgens*, but it was not so named. I do not marvel, however, that Mr. Gorrie did not recognise it, but described it as "*R.*—?, an unnamed species," for it is unlike both the types alluded to above. The plant which Mr. Gorrie named *R. fulgens* may possibly be yet another form of the species; but if so, it is a fourth form. His description is as follows:—"*R. fulgens*—a plant which is now about twenty-five years old, and only 15 inches in height by 33 inches in diameter—has never suffered from either winter or spring frosts, nor has it yet flowered, but its compact growth and the bright verdigris-green of its young leaves render it a favourite dwarf evergreen."

Once again, Mr. Luscombe has been growing Sikkim Rhododendrons from the very first, and his plants are, or were, of the first generation. He has written to me on the subject of *R. fulgens*, and he tells me that his type of the species is, "not like that in Sir J. Hooker's work, but loose-flowering like *R. Thomsoni*." Now, considering that Sir J. Hooker's *R. fulgens* has a cluster of many flowers crammed closely together, and that *R. Thomsoni* hangs its few flowers as loosely as may be, this is saying a great deal. Mr. Anderson-Henry considers that he has two or three varieties of the species, and not many weeks ago I discovered in Mr. Rogers' most picturesque nursery, near Southampton, a form which in foliage seemed different from all that I have described. But as this last was a grafted plant, I must not rely too much on its appearance. At Kew, there are several types, which with the kind assistance of the authorities I propose to study during the ensuing season.

Similar remarks might be made with regard to other species, such as *R. argenteum*, Falconeri, Thomsoni, and others; but I must postpone these for the present, and devote a few words to my explanation of the facts as illustrated by the example of *R. fulgens*. I may be wrong, but, if so, I have the satisfaction of knowing that a most competent observer, who is much interested in the subject, will probably find this very spring be in a position to confute me on the spot. The explanation, then, is this:—That as the Himalayan range passes eastward through Nepal, Sikkim, and Bhotan, the genus Rhododendron becomes truly protean in form, and presents not only an extraordinary number of species in a small space, but also striking geographical varieties in very great abundance. Even *R. arboreum*, which, according to Dr. Thomson, is so uniform, except in colour westward, begins to yield to variation in Nepal. On some future occasion I may show how this notion of extreme variety is quite in accordance with high authority, and especially with the writings of Sir J. Hooker (who mentions the case of *R. Falconeri*, *R. Aucklandii*, and others), and I may then point out the curious resemblances, and yet the differences, between the Rhododendrons of Sikkim and Bhotan, which have now been brought together in the *Flora of British India*. For the present I will only add that the circumstances attending the collection of Rhododendron seed, and the fact that ripe seed and blossoms are seldom to be seen together, will explain how many smaller differences have escaped the observation of collectors who have gathered the same species from different localities, from different elevations, or perhaps from different sides of the same valleys. Such an explanation is surely more philosophical than the notion that so many variations have arisen—not gradually, but all of a sudden—from cultural influences. My readers will apprehend how interesting botanically it is to find such a variety of types packed together in so small a compass, for instance, as Sikkim; but they will, of course, remember the character of the country and its climate, where alpine and almost tropical conditions occur side by side. The Heaths at the Cape of Good Hope give an example of great variation in the same family, but Dr. Beccari's remark on the Rhododendrons of Borneo offers the best, and a very curious, analogy.

His words are very striking:—"According to my personal observations it appears that almost every mountain top in Borneo has its own special forms, which do not seem to spread themselves, at least on the adjoining mountains." *J. H. Mangles, Valewood, Haslemere.*

SPRING-FLOWERING RHODODENDRONS.—On March 16, 1878, we devoted an article to the description of various early-flowering Rhododendrons, including *R. dahuricum*, *R. precox*, and *R. Early Gem*. We need not repeat the history and descrip-

FIG. 39.—RHODODENDRON DAHURICUM.

tions then given, but as reminders of these very useful plants we may now give figures of *R. dahuricum* (fig. 39), which is a natural species, and *R. precox* (fig. 40), which is a hybrid between *R. da-*

FIG. 40.—RHODODENDRON PRECOX.

huricum and *R. ciliatum*, raised by Mr. Davies, of Ormskirk. *R. dahuricum* blooms about a fortnight earlier than *precox*, while *R. ciliatum* is later still. Both of these, as well as *R. Early Gem* (figured at p. 335, March 16, 1878), are most useful in the spring garden and for forcing purposes. *R. precox* often flowering under such circumstances in November.

THE WEST OF SCOTLAND PANSY SOCIETY'S SHOW will be held in the City Hall, Candleriggs, Glasgow, on Wednesday, July 26.]

LAYING BOX EDGINGS.

So many substitutes have from time to time been recommended to take the place of Box edgings in gardens, that had not universal taste been overwhelmingly in favour of the latter it would probably have in great measure long ago disappeared from our gardens. Stone or tile edgings may possibly be cheaper in the end than Box, but they will not bear comparison with the natural appearance of Box when neatly laid and kept in proper order. There are, however, exceptional cases where it would be not only true economy, but also something gained in appearance, to discard the Box—as, for example, in a stiff, clayey soil, where Box seldom remains long in good health, and a stone or tile edging is certainly preferable to a patchy Box one. But in these days of economy and retrenchment in gardens it is hardly worth while discussing seriously any present probability of stone or tile edgings taking the place of Box in gardens of any considerable extent. If I had only my own personal taste to consult, I would not hesitate to undertake a little extra labour in planting the Box, to the extent of replacing an ungenial soil with one of a more suitable nature, rather than look at the majority of clumsy-looking edgings that I have seen substituted for Box.

It is hardly necessary to point out the importance of having neat edgings in every cultivated garden, nor is it too much to say that the garden that is without them lacks one of its greatest and most conspicuous ornaments. We have now arrived at a season when Box planting may be undertaken with every prospect of success. Box laying in autumn is rather a risky business unless the soil is light and very dry, and the plants are well rooted. Severe frost claims a heavy mortality among newly laid plants; or, if it is not severe enough to kill them outright, they are often disfigured by the green leaves turning white, and do not regain their normal colour until the season is far advanced. For this reason Box planting upon an extensive scale is best performed during the spring months, when plants having the semblance of a root at all are sure to grow and flourish. I may here mention (although it is somewhat digressing from my text) that people who are in a hurry to "clip" their Box edgings sometimes get nipped by late frosts in May, which sadly disfigure the lines of Box for some time afterwards. But considerable judgment must be exercised in regard to the character of soil and climate. It will always pay those who are engaged in such work to take well their bearings as regards locality, and to look up the average degrees of frost annually registered in the neighbourhood, because what would be safe practice in one place might be the opposite in another.

Assuming, then, that a whole garden, or any portion of it, requires to be relaid, it would be well, if possible, to have the ordinary work well in hand, in order to be able to give concentrated attention to Box planting in fine weather. Two good men will get through more planting in a favourable week than they would otherwise accomplish in double the time, with more satisfaction generally, and better results in the end. To begin with, the gravel should be removed from the line of Box to the centre of the walk, and straight sticks from 1 foot to 18 inches in length should be inserted about the centre of the line at distances of from 10 to 15 yards apart. The sticks indicate to the workman his position while the ground is in process of being prepared for replanting. In cases where the Box has been neglected and has grown naked at the bottom there may be some difficulty in selecting suitable plants to relay the lines over again, in which case all plants that are obtainable with roots should be laid together, whilst those plants having little or no roots should be planted by themselves. If the spring should turn out a genial moist one the chances are that plants having very few roots will succeed equally well with those that are well rooted, but in any case the worst plants that can be imagined may be grown into useful stock in a season. All that is necessary is to lay or "heel them in" sufficiently deep to cover the naked portion of the stems, which, as may be observed by any one, are already covered with little white specks like warts, in reality young rootlets only requiring the natural conditions of soil and moisture to cause them to grow. In a season, then, these plants are grown into valuable stock.

It may be as well to state, for the benefit of those who have to purchase Box for laying, that it costs

about 6z. the running yard, and that one yard will lay three or thereabouts. With regard to the preparation for planting it is important to go about the work methodically and in the simplest manner possible. The operation, from beginning to end, should be directed by some one of experience, and above all things he should have a quick eye for levelling. This is especially necessary in dealing with walks having steep gradients, where a sharp eye is worth a whole set of levelling tools. A simple way of proceeding is to take levels at, say, 15 to 20 yards apart, which will be sufficiently near to guide the workman in preparing and levelling the ground. Beginners will avoid complications by simply calculating that the height of the newly laid Box should be about level with the centre of the walk. It is specially recommended that the ground should be properly dug about 6 inches upon either side the run of the line, and that every stone should be picked out that is likely to obstruct the downward passage of the spade when the trench or cut is being made to lay in the plants. Having done this the earth will have to be firmly trodden with the feet, and brought to within a shade of level with the sticks at the different points where levels were taken. Before proceeding further raise the earth round the pegs indicating the levels up to their proper height, viz., flush with the tops of the pegs, and then lay down a strong line and peg it close to the ground at each level. After this it is only necessary to fill in between the pegs, pressing the soil firmly until the line when freed dangles upon the surface from one end to the other.

The next step for consideration will be the making of the plants, which for "neat work" should be done by those who are about to lay them. This can be done during the mornings and evenings, or during wet days, when it is not practicable to work out-of-doors. No workman should be allowed to make or prepare plants who has not had some practice in laying. The plants should be made of equal length and thickness, and trimmed level upon the top, so that the line, when laid, will present an even surface. A sufficient number of plants being ready the line should be re-laid in its proper position, and tightened as much as the cord will bear, and then "pegged firmly down at every level point," in order that it may not be disturbed during the process of planting. The trench should then be cut flush with the line and slanting slightly inwards at the bottom, so that when the plants are pressed after being laid they take a perfectly perpendicular position. No more than one hand should be employed upon the same line unless in case of workmen who have had considerable practice together. After the plants are laid press them firmly at their roots, then fill in the spare soil which, when pressed firm as a board, should be sloped down with the spade from the line of Box in the direction of the walk, leaving a good margin of soil at the base of the cut for the roots of the Box to grow in. Then fill in with stones or rubble, and bring the gravel back to its former position.

It should be stated for the benefit of amateurs and others that Box should always be laid with its roots towards the walk whether in small designs or in ordinary cases of relaying the edges of garden walks. Happily for gardeners and gardeners those Dutch gardens and scrolls laid in treble lines of Box have grown obsolete. I can remember being on my knees for ten weeks at one spell, assisting to lay one of those namby-pamby doll gardens, and looking back now with the experience of twenty years I can only say the garden was dear at the price. We first prepared the ground roughly, marked out the lines where the Box was to be laid, dug and cleared it of stones in the run of the line of Box, then firmed and levelled the whole surface and laid down the design. But what is advocated here is that it is worth an effort at this the most favourable season of the year to renew the edgings of walks with neatly laid Box, which together with clean well rolled walks are the most pleasing features of a well kept garden. *H. Hutt.*

PEAR JALOUSIE DE FONTENAY.—Mr. Baron remarks in the *Florist and Poinsettist* that there are few better Pears than this, which is one of the oldest of our high-class varieties, and yet is comparatively unknown. It is not a sensational Pear, but, like the Winter Nells, it is always good. The fruits are somewhat below the size in fashion at the present time, and it has the misfortune to come into use in October, when good Pears are abundant.

EMBER COURT.

THIS charming country seat, the residence of C. J. Corbett, Esq., is situated in a beautiful and fertile district about half-way between Thames Ditton and Esher railway stations, and about 2 miles distant from Hampton Court Palace. The estate is of considerable historical interest, as may be seen from a perusal of the history of Surrey. The present proprietor has occupied the place over twenty-one years, during which time important additions have been made to the gardens and grounds. The carriage-drive leading to the mansion is approached from the Esher Road through substantial iron gates fixed into strong square stone pillars. The drive curves gently to the east front, from which there is a good view of the park, which is fertile in appearance, and well timbered. The house is a plain but substantial edifice of brick, partly stuccoed, with extended wings of a uniform character. The ceilings of the front hall are fitted up in the arabesque style, and the mansion contains a large collection of pictures.

The grounds upon the south side contain good specimens of *Abies cephalonica*, fine *Wellingtonias* and *Araucarias*, and at the south-west angle, outside the conservatory, a huge specimen of the *Oriental Plane*. The conservatory and fernery in three divisions run east and west, and communicate with the mansion, the fernery being very artistically arranged in the inside with cascades and rockwork. The conservatory is a large oblong structure, ornamented with creepers upon the roof of *Coccoloba scandens*, *Tecoma jasminoides*, *Hibiscus thurberi*, *Lapageria*, &c., and well furnished with fine Palms, Tree Ferns, *Musa Ensete*, *Spathoglaphis africana*, and other winter-flowering subjects. Orange trees and tall *Aralias* have also a good effect in this structure. In the three divisions of the fernery the principle of planting is the same throughout—projecting pieces of rock with pockets containing a handsome specimen Fern, and having a groundwork of *Selaginella Kraussiana*, and the jungles among the rocks treated in a similar way. The effect produced is largely owing to the fact that but few large Ferns are used, while the groundwork of medium-sized plants and the carpet of *Selaginella* is elaborate. The sides of the structure are also made to have a rustic appearance, by fastening pieces of cork to the woodwork, upon which dwarf-growing Ferns and mosses are kept green and fresh by supplying them with plenty of moisture. The passage from the fernery into the drawing-room is exceedingly pretty. As you ascend the steps the rockwork is composed of *Delry-side spar*, and is beautifully clothed with Ferns and mosses.

Flower gardening is carried out in a series of beds cut out of the margins of the lawns, and in geometrical groups in other portions of the grounds, which are also furnished with valuable ornamental trees and plants. In fact, flowers of one kind or another and trees and shrubs are closely associated with each other over the whole area of the dressed grounds, with more than ordinary taste and skill. The chief attraction of the grounds lies, however, in the meanderings of the Mole, or, rather, of the river Ember, a tributary of the Mole. Outside the conservatory, on the river's brink, stands a fine group of *Nymph Elms*; and following the course of the river through the grounds in a northerly direction are some fine specimen Conifers and a stump of a fine old Willow (*Salix alba*) which was blown down about a year ago. The stump is over 4 feet in diameter, or 12 feet 6 inches in circumference, according to the ordinary rule of calculation. This is thought to be an extraordinary size for a tree of its kind.

In the north side of the grounds the "nut-walk and roseray are said to be very pretty when in leaf, as also a large *Viburnum* planted against the north wall of the kitchen garden, which is 4 feet in diameter at 2 feet from the ground, and which covers a length of wall 27 yards in length, besides covering a framework, 10 yards in diameter, the same length. The branches are supported by stakes about 7 feet high from the ground, and a design underneath is planted with hardy ornamental shrubs.

Leaving the kitchen garden on the right, and pursuing the course of the river, which is spanned by several rustic bridges, the northern extremity of the grounds is reached, where there are some grand specimens of *Thuja Lobbi*, 50 feet high; *Cupressus Lawsoniana* and *macrocarpa*, a fine *Abies cephalonica*, and several good *Wellingtonias*. In these (commonly called the new) grounds spring

bedding and flowering shrubs are the chief feature. One must omit many things of interest in a brief notice of this kind, but before entering the kitchen garden I must mention a noble tree of *Taxodium distichum* by the brink of an outlet of the river, which is remarkable for its size, but it is feared it is in declining health.

The kitchen garden is a very compact walled-in oblong figure, divided into the usual quarters for the cultivation of fruits and vegetables. The walls are in excellent order, as also the trees, which are neatly trained, and the espalier-trained trees bear evidence of the same skilful treatment. The forcing houses are within the walls of this garden, and are in capital repair, and their occupants generally in first-rate order. The south wall is entirely covered in with glass for forcing Figs, Grapes, Peaches, and other fruits. One of the divisions is devoted to plant growing, and contains well cultivated samples of popular stove plants.

The second range is about equally divided between cultivating plants and fruits. Of the latter Pines, Grapes, Peaches, and Strawberries, may be mentioned; and of the former Orchids, Ferns, and miscellaneous plants generally. There are several detached forcing pits which are found useful, and a fine spanned structure for growing Pines and New Holland plants.

In the division with the Pines Cucumbers are well grown in boxes placed over the hot-water pipes and trained up both sides of the roof. In the cool division there is a good show of seasonable flowers upon the side stages, while the centre stage is arranged with New Holland plants in considerable variety, intermixed with other flowering plants, which add immensely to the appearance of the house, and bear testimony to the skill of the cultivator (Mr. Bigg), who has been head gardener at the place for over nine years. *Albion.*

PYRETHRUM INSECT-POWDER.

THERE are very few data at hand concerning the discovery of the insecticide properties of *Pyrethrum*. The powder has been in use for many years in Asiatic countries south of the Caucasus mountains. It was sold at a high price by the inhabitants, who successfully kept its nature a secret until the beginning of this century, when an Armenian merchant, M. Juntikoff, learned that the powder was obtained from the dried and pulverised flower-heads of certain species of *Pyrethrum* growing abundantly in the mountain region of what is now known as the Russian province of Transcaucasia. The son of M. Juntikoff began the manufacture of the article on a large scale in 1825, after which year the *Pyrethrum* industry steadily grew, until to-day the export of the dried flower-heads represents an important item in the revenue of those countries.

Still less seems to be known of the discovery and history of the Dalmatian species of *Pyrethrum* (*P. cinerarifolium*), but it is probable that its history is very similar to that of the Asiatic species. At the present time the *Pyrethrum* flowers are considered by far the most valuable product of the soil of Dalmatia.

There is also very little information published regarding either the mode of growth or the cultivation of *Pyrethrum* plants in their native home. As to the Caucasian species, we have reason to believe that they are not cultivated—at least not at the present time—statements to the contrary notwithstanding.* The well-known Dr. Gustav Radde, Director of the Imperial Museum of Natural History at Tiflis, Transcaucasia, who is the highest living authority on everything pertaining to the natural history of that region, wrote us recently as follows:—"The only species of its genus—*Pyrethrum roseum*—which gives a good effective insect powder, is nowhere cultivated, but grows wild in the basal-alpine zone of our mountains at an altitude of from 6000 to 8000 feet." From this it appears that this species, at least, is not cultivated in its native home, and Dr. Radde's statement is corroborated by a communication of Mr. S. M. Hutton, Vice-Consul-General of the United States at Moscow, Russia, to whom we applied for seed of this species. He writes that his agents were not able to get more than about half a pound of the seed from any one person. From this statement it may be inferred that the seeds have been

* *Re. et Comm. of Patents, 1857, Agriculture, p. 128.*

gathered from the wild and not from the cultivated plants.

As to the Dalmatian plant it is also said to be cultivated in its native home, but we can get no definite information on this score, owing to the fact that the inhabitants are very unwilling to give any information regarding a plant the product of which they wish to monopolise. For similar reasons we have found great difficulty in obtaining even small quantities of the seed of *P. cinerariifolium* that was not baked or in other ways tampered with to prevent germination. Indeed, the people are so jealous of their plant that to send the seed out of the country becomes a serious matter, in which life is risked.

The seed of *Pyrethrum roseum* is obtained with less difficulty, at least in small quantities, and it has even become an article of commerce, several nurserymen here, as well as in Europe, advertising it in their catalogues. The species has been successfully grown as a garden plant for its pale rose or bright pink flower-rays. Mr. Thomas Meacham, of Germantown, Pa., writes us:—"I have had a plant of *Pyrethrum roseum* in my herbaceous garden for many years past, and it holds its own without any care much better than many other things. I should say from this experience that it was a plant which will very easily accommodate itself to culture anywhere in the United States." Mr. Peter Henderson, of New York, another well-known and experienced nurseryman, writes:—"I have grown the plant and its varieties for ten years. It is of the easiest cultivation, either by seed or division. It now ramifies into a great variety of all shades, from white to deep crimson, double and single, perfectly hardy here, and I think likely to be nearly everywhere on this continent." Dr. James C. Neal, of Archer, Fla., has also successfully grown *P. roseum* and many varieties thereof, and other correspondents report similar favourable experience. None of them have found a special mode of cultivation necessary. In 1856 Mr. C. Willemot made a serious attempt to introduce and cultivate the plant* on a large scale in France. As his account of the cultivation of *Pyrethrum* is the best we know of, we quote here his experience in full, with but few slight omissions:—"The soil best adapted to its culture should be composed of a pure ground, somewhat siliceous and dry. Moisture and the presence of clay is injurious, the plant being extremely sensitive to an excess of water, and would in such case immediately perish. A southern exposure is the most favourable. The best time for putting the seeds in the ground is from March to April. It can be done even in the month of February if the weather will permit it. After the soil has been prepared and the seeds are sown they are covered by a stratum of earth mixed with some vegetable mould, when the roller is slightly applied to it. Every five or six days the watering is to be renewed, in order to facilitate the germination. At the end of about thirty or forty days the young plants make their appearance, and as soon as they have gained strength enough they are transplanted at a distance of about 6 inches from each other. Three months after this operation they are transplanted again at a distance of from 14 to 20 inches, according to their strength. Each transplantation requires, of course, a new watering, which, however, should only be moderately applied. The blossoming of the *Pyrethrum* commences the second year, towards the end of May, and continues to the end of September." Mr. Willemot also states that the plant is very little sensitive to cold, and needs no shelter, even during severe winters.

The above-quoted directions have reference to the climate of France, and as the cultivation of the plant in many parts of North America is yet an experiment, a great deal of independent judgment must be used. The plants should be treated in the same manner as the ordinary *Asters* of the garden or other perennial Compositae.

As to the Dalmatian plant, it is well known that Mr. G. N. Milco, a native of Dalmatia, has of late years successfully cultivated *Pyrethrum cinerariifolium* near Stockton, Cal., and the powder from the California-grown plants, to which Mr. Milco has given the name of "Bulnach," retains all the insecticidal qualities, and is far superior to most of the imported powder, as we know from experience. Mr.

* Mr. Willemot calls his plant *Pyrethrum du Caucase* (*P. Willemoti*, Duchroite), but it is more than probable that this is only a synonym of *P. roseum*. We have drawn liberally from Mr. Willemot's paper on the subject, a translation of which may be found in the report of the Commissioner of Patents for the year 1854, Agriculture, pp. 223-331.

Milco gives the following advice about planting—advice which applies more particularly to the Pacific coast—"Prepare a small bed of fine, loose, sandy, loamy soil, slightly mixed with fine manure. Mix the seed with dry sand, and sow carefully on top of the bed. Then with a common rake disturb the surface of the ground half-an-inch in depth. Sprinkle the bed every evening until sown; too much water will cause injury. After it is well sprouted, watering twice a week is sufficient. When about a month old, weed carefully. They should be transplanted to loamy soil during the rainy season of winter or spring."

Our own experience with *P. roseum* as well as *P. cinerariifolium* in Washington, D.C., has been so far quite satisfactory. Some that we planted last year in the fall came up quite well in the spring, and will perhaps bloom the present year. The plants from sound seed which we planted this spring are also doing finely, and as the soil is a rather stiff clay, and the rains have been many and heavy, we conclude that Mr. Willemot has overrated the delicacy of the plants.

In regard to manufacturing the powder, the flower-heads should be gathered during fine weather when they are about to open, or at the time when fertilization takes place, as the essential oil that gives the insecticidal qualities reaches, at this time, its greatest development. When the blossoming has ceased the stalks may be cut within about 4 inches from the ground and utilized, being ground and mixed with the flowers in the proportion of one third of their weight. Great care must be taken not to expose the flowers to moisture, or the rays of the sun, or still less to artificial heat. They should be dried under cover and hermetically closed up in sacks or other vessels to prevent untimely pulverization. The finer the flower-heads are pulverized the more effectually the powder acts and the more economical is its use. Proper pulverization in large quantities is best done by those who make a business of it and have special mill facilities. Lehn & Fink, of New York, have furnished us with the most satisfactory powder. For his own use the farmer can pulverize smaller quantities by the simple method of pounding the flowers in a mortar. It is necessary that the mortar be closed, and a piece of leather through which the pestle moves, such as is generally used in pulverizing pharmaceutical substances in a laboratory, will answer. The quantity to be pulverized should not exceed 1 lb. at a time, thus avoiding too high a degree of heat, which would be injurious to the quality of the powder. The pulverization being deemed sufficient, the substance is sifted through a silk sieve, and then the remainder, with a new addition of flowers, is put in the mortar and pulverized again.

The best vessels for keeping the powder are fruit jars with patent covers, or any other perfectly tight glass vessel or tin box. C. V. Riley, in "*American Naturalist*."

(To be continued.)

PLANT PORTRAITS

ALOCASIA PUTZEYSII, N. E. Brown, sp. n., *Illust. Hort.*, t. 439.—A Javanese Aroid, with stalked petiolate leaves, 1-1½ foot long by 6-7 inches wide, hastate ovate lanceolate acute, dark green, with a light green edge, and with the nerves remote from one another and white; the under-surface is of a dark violet colour. Introduced by M. Linden.

CAMBISEDESIA PARAGUAYENSIS, Hook. f., *Bot. Mag.*, t. 6604.—A Melastomaceae shrub, with small sessile ovate acute ciliate leaves, and terminal many-flowered cymes of rosy-lilac flowers about 1 inch across. Native of Paraguay. Messrs. E. G. Henderson & Son.

CAMELLIA GUISEPPINA MERCATELLI, Full So., *Toscana di Orticultura*, October.—Flowers white, sparingly striped with red, moderate in size, very double, and very symmetrically imbricated, inner petals somewhat pointed, outer ones rounded, faintly crenulate.

GYNURA AURANTIACA, *Illust. Hort.*, t. 436.—A remarkable Javanese Composite perennial, with a thick fleshy stem and shortly stalked ovate acute coarsely toothed leaves, pilose, and of a violet or purple tint except near the apices. It is suspected that it will be a good plant for summer bedding. Hort. Linden.

HIBISCUS ROSA SINENSIS, Lucien Linden, *Illust. Hort.*, t. 447.—Flowers large, very double, yellowish, striped and variegated with brilliant red markings.

IRIS SUSIANA, Berlin *Monschrift*, December. *LESPEDEZA BICOLOR*, Turczaninow, *Bot. Mag.*, t. 6602.—A hardy Papilionaceous shrub, native of North-eastern Asia, with glabrous 3-foliolate leaves with oblong leaflets. The flowers are numerous in branched panicles, each about the size of the flower of a *Vetch* and of a rosy-purple colour. Hort. Kew.

MASDEVALLIA SHUTTLEWORTHII, *Illust. Hort.*, t. 435.—Flowers yellowish, with broadly ovate segments, striped spotted and barred with red, and prolonged into very long slender tails. See *Gard. Chron.* 1875, v. 1, 1704 1876, vol. ii., 782.

NECTARINE PEACH, *Illust. Hort.*, t. 440.—Fruit of medium size, quite glabrous, like a Nectarine, golden-yellow, brilliant and shatter soft. Flesh very juicy, greenish-white, darker towards the centre.

PEAR JULES D'AIROLES (Leon Leclerc), *Lull. d'Arboretum*, January, 1882.—Fruit large, pyriform oblique, brilliant red on the sunny side, eye shallow, stalk stout, short; flesh white, juicy, of first quality. Season, December.

TOMATO TRENTHAM EARLY FILLBASKET, *Florist and Pomologist*, December.—A cross between *Criterion* as the seed-parent, and *Triophy* as the pollen-parent. It has the fine flavour and colour of the latter with the productiveness of *Criterion*. Raised by Mr. Stevens, of Tientham.

SHOREHAM PLACE.

SHOREHAM PLACE, near Sevenoaks, Kent, is situate about half a mile from the Shoreham station on the London, Chatham, and Dover Railway, and is the residence of H. E. Midday, Esq. The neat and practical manner in which gardening is carried out there is at once evident when the garden is entered, and in the various plant-houses may be seen many novelties of sterling merit, and which are also well grown. The flowering-house is a span-roofed structure 50 feet by 20, and is very gay with *Amaryllis*, *Cyclamen*, *Primulas* (Williams' *alba magnifica* and *rubro-violacea*, very fine), *Carnations* of sorts, *Cinerarias*, *Callas*, *Deutzias*, *Epacris*, *Salvias*, *Lilacs*, *Rhododendrons*, *Azalea indica* and *mollis*, *Abutilons*, *Gaultheria Rose*, *Lilium trigynum*, and that grand old *Pelargonium Rolisson's Unique*, intermixed with *Camellias* and *Lilacs*, form a very nice display. The *Orchid*-houses are also very gay, amongst others in flower being *Cypripedium boxalli*, *C. insigne* (a fine variety with three dozen flowers), *C. villosum* (with two dozen blooms), *Coleogyne cristata*, *Vanda gigantea*, *Dendrobium Wardianum*, *D. noble*, *Lycaste Skinneri*, *Calanthe Veitchii* and *vestita*, *Vanda superba* and *tricolor* (fine varieties), *Phalenopsis Schilleriana*, *Dendrobium glumaceum*, *Lalia Filcheri* (rare), *Cypripedium barbatum*, *Odontoglossum crispum* (many varieties), *Oncidium*, &c. These mixed with flowering plants of *Begonia odorata*, *nitida* and *manicata*, and several good Ferns, form a very imposing sight. The various growths in other varieties of *Orchids* show that they receive the attention they require; the cool *Orchids* are done remarkably well, and are grown in quantities for cutting purposes.

The stove contains a very fine collection of well-coloured *Dracenas* and *Crotons*, *Palms*, and other fine-foliage-plants. Flowering plants are also well represented. Fine specimens of *Anthium Scherzerianum*, *Eucharis*, *Dipladenias*, *All. mandas*, &c., are most noticeable; and winter flowering *Begonias* are grown extensively, as also are *Thyrsacanthus rutifolius*, *Centropogon Lucyanus*, and such-like—these at this dull season of the year are very useful; a lean-to house planted with *Roses*—*Niphetos*, *Marichal Niel*, *Gloire de Dijon*, being particularly fine just now, and have been so all the winter. The fruit-houses are promising to produce good crops; *Peaches*, *Nectarines*, and *Figs*, are well set, and the *Vines* look remarkably well, carrying a good crop, clean, strong, and healthy.

Noticeable also in a late *Peach*-house are fine specimens *Ericas*, *ampullacea*, *cerinthoides*, *coronata*, &c., making fine growth. The various pits and frames are full of good useful flowering plants, suitable for cutting purposes. The forcing department is also now busily engaged. *Beans*, *Melons*, *Cucumbers*, and *Strawberries* are grown in great quantities, and are producing fine crops. The whole of this establishment is well done; it has been under the management of Mr. James Burt for sixteen years, and the condition of both indoors and out reflects great credit on his abilities as a gardener. U.

THE HERBACEOUS BORDER.

OMPHALODES VERNA.—This pretty spring flowerer, which is now in full bloom here, like many other things, fully a month before its usual time, will be thought by many too common and too easily grown to require any notice. Yet how many gardens are without it, and in mine, for one, it used to be planted nearly every year only to perish before the next. Two years ago, I was at Grange-over-Sands, where the gardens are full both above and below ground of limestone rocks, about the edges of which this plant ran and flourished so luxuriantly as to become in some spots a troublesome weed. It did nowhere better than at the edges of drives covered with gravel and bounded by rocks. I had supposed from its resemblance to a *Myosotis* that it liked a damp and shady spot, and I am prepared to hear that it does well in such places in some gardens; but here the clouds give enough shade, and there is too much damp. However, I brought a large supply from Grange, and planted it everywhere. The finest hatch is where it has strayed into a gravel walk on the upper ledge of a steep bank, a very well drained spot. But I have 200 or 300 yards of edging made of common square blue Staffordshire tiles. The soil on the border side of these is level with the top of the tile; on the other side, the walk is 4 inches below the top of the soil. When planted at the edge of the border quite against the tile, many rock plants which I cannot grow generally on a flat border seem quite at home, and grow over the edge down to the gravel. This is the place that just suits *Omphalodes verna*. It runs along the edge of the tiles, sending up its suckers as it goes, which again send their flowering shoots to hang over the side, and make what would otherwise be an ugly edging very ornamental. It requires, however, trimming and thinning, and replanting occasionally; for when it takes to a spot, the multiplication of its shoots is tremendous. *C. Wulley Dol, Edge Hall, Malpas.*

PULMONARIAS.—The variety sold as *P. saccharata grandiflora*, and also having several other names (the oldest and most correct, if I mistake not, being *P. officinalis* var. *caucasica*), is perhaps the most showy of the many varieties of Lungwort. It is remarkable for being this year ahead of the other varieties in its time of flowering, having been fully out since the beginning of February. Two years ago a native form common in woods near Poole in Dorsetshire, whence I had it, was equally ahead of the others. In Bentham's *British Flora* it is stated that the two forms recognised as native, generally called *P. officinalis* and *P. angustifolia*, are only varieties of one species, and that intermediate forms are found in different parts of Europe connecting them. Having done my best to collect all the *Pulmonarias* in cultivation in England, I am disposed, as a gardener, to agree with Mr. Bentham. I except, of course, the plants now generally called *Mertensias*, and the delicate and rare *P. dahurica*, but I think that of the others—more than a dozen in number, and still more in name—a series may be formed, between the links of which it is difficult to draw a line. *Pulmonarias* vary a good deal according to soil and situation, and probably most of the so-called species are local varieties found wild in some parts of Europe or Asia. *Pulmonarias* are very unwilling to make seed in the garden, and I believe in England generally. Being asked for some seed for scientific purposes I searched all my plants last year, and a single seed, which was lost in transit, was all I was able to send. The very early flowering of *Pulmonarias* is to be regretted, as the colour of the flowers is spoilt by frost, though the plants do not suffer. *C. Wulley Dol, Edge Hall, Malpas.*

BORAGO ORIENTALIS.—Amongst the most conspicuous of outdoor herbaceous plants now in flower is the subject of the present note. It is quite hardy, but the pretty blue blossoms are sometimes discoloured and spoilt if severe weather sets in after they have opened. It grows about a foot high, and will take care of itself in the front of the ordinary shrubby border. It is a native of Eastern Europe and Western Asia, and was cultivated in the Chelsea Botanic Garden in 1752.

THE BURTON-UPON-TRENT HORTICULTURAL SOCIETY'S FLOWER SHOWS will be held this year on June 21 and August 23.

SALIX BASFORDIANA.

UNDER the name *Salix Basfordiana*, the well-known Willow nurseryman, Mr. Scaling, has for many years distributed a very beautiful Willow which deserves general cultivation. Under the name *Salix sanguinea*, Mr. Scaling also sells another Willow having the closest resemblance to the first. The one is male and the other female; and I am satisfied they are the two sexes of the same species. I have not succeeded in finding any scientific description of this Willow, and I propose to describe it now under the appellation given to the male plant, *S. Basfordiana*.

When I first received this Willow from Mr. Scaling in 1871, he informed me that he had found it some years before growing in the Forest of Ardennes,

FIG. 41.—SALIX BASFORDIANA, HORT. 1. MALE.

in the North of France, from whence he subsequently obtained cuttings.

Salix Basfordiana belongs to the section of the Willows called "Fragiles," which, by the way, very little deserves the appellation: it is especially inapplicable to the species now under consideration. It grows of considerable height in a broad pyramidal shape: the foliage is bright, abundant, and handsome. But the most striking beauty of the tree is the bark, which is brilliant orange passing to red in the terminal twigs, with a shining, polished surface. The colour is very remarkable, and altogether surpasses that of our Golden Osier—*Salix vitellina*. The bark of the female plant is rather darker than in the male, especially on the small terminal branches. The female tree is slightly less vigorous in growth than the male, and perhaps rather less hardy.

Salix Basfordiana has considerable resemblances to three of our native *fragilis*. The foliage and glossy smoothness of the bark—though not its colour—

resemble *S. decipiens*: the female catkins and ovaries are very like those of *S. Russelliana*, while the male catkins resemble *S. fragilis*.

The early foliage and the catkins appear together, usually about the third or fourth week of April. The leaves are lanceolate, pointed, slightly serrated, and very glabrous. When the growth is very vigorous large stipules are produced; but they are often entirely wanting. The young twigs and the developing leaves are frequently stained with crimson, as in *S. decipiens*.

Female catkins cylindrical, about 1½ inch long. Ovaries adpressed to the axis, as in *S. Russelliana*. Scales smooth, very slightly ciliated at the edge, or not at all, about two-thirds the length of the ovary. Germen nearly sessile, lanceolate, smooth, closely resembling *S. Russelliana*. Style longer than the bifid stigma.

Male catkins cylindrical, often reaching 2½ inches in length. Scales slightly ciliated, about half the length of the stamens. The male catkins are handsome, abundant, pale yellow, with an agreeable perfume, and are much frequented by bees.

The provisional name, "*Basfordiana*," has been given to the Willow, after the parish, Basford, Notts, in which Mr. Scaling resides, and where he cultivates an enormous collection of species and varieties of *Salices* with great success.

This is the best season of the year for planting Willow cuttings, and it should be known that cuttings succeed far better than rooted trees transplanted. *James Salter, F.R.S., Basingfield, Basingstoke.*

[We have submitted the drawings to M. Crépin, the Director of the Brussels Botanic Garden, the authority for plants of the Ardennes, but that gentleman is not able to give an opinion as to the identity of this form. ED.]

Notices of Books.

The Names of Herbes.

MR. BRITTON has edited for the English Dialect Society a reprint of William Turner's treatise on this subject, which dates as far back as 1548. Indexes giving the modern names of the plants are added, the necessity for which is apparent from the title-page, which runs thus:—"The Names of herbes in Greke, Latin English, | Duch & Frenche, wyth | the commune names | that Herbaries | and Apothecaries use. Gathered by William Turner." The book is dedicated, in the long-winded and fulsome style then prevalent, "To the mooste | noble & mighty Prince Edward | by the grace of God Duke of Summerset, | Erl of Hertford, Vicount Beuchamp, | Lord | Semour uncle unto the Kynges highnesse | of Englands, governor of his most roy | all person, and Protector of al his realmes | dominions and subiectes," &c. The book was written "from your grace's house at Syon, anno Dom. M^{CC}XLVIII," and it is interesting to find a park, still renowned for its fine trees, even at that time enjoyed a similar renown. Thus we are told that "Cypresses growe in great plenty in my Lordes graces gardine at Syon." Of "Pomgranat trees" also, which "growe plentifully in Italy and in Spayne," we are told that "there are certayne in my Lordes gardine at Syon, but their fruit cometh neuer unto perfection." The Fig tree was in cultivation at that time also, as we learn from the following extract:—"Ficus is called in Greke Syce, in English a Fig tree, in Duch ein figge baume, in frinch vng figuier. There are diuers Fyg trees in Englands in gardines, but nowhere els." Strawberries also were common enough, for we read that "Every man knoweth we inough where Strawberies growe."

Of Narcissus it is stated that there is one "wyth a white floure, which groweth plentifully in my Lordes gardine in Syon, and it is called of diuers, wythe Laas tibi; it maye also be called wythe daffadyll."

The list will prove useful to those seeking the history of the introduction of various plants. Thus, while the Larch, the Fir, and the Pine—of which latter we are told, by the way, that "there groweth one fayre one in Richmund"—are all mentioned—in some cases as "plated and set by mannes hande, both in England and in Germanie"—no mention is made of the Cedar. As to the *Platanus*, Turner tells us he "never saw any plaine tree in Englands sauing one in North-umberlande besyde Morpeth, and another at Barnwel Abbey besyde Cambrige." In reference to "radix," Radishes, it appears that while the long kinds were

common in England at that time, "the other kynde [with], a rounde root lyke a rape . . . called radix Beotia and radix Syriaca" had only been seen by the author "no where els sayunge only in high Almany [Germany]." Turner, like many of his successors, and with as little success, sought to impose English names where there were none. Asparagus, the Asperge of the French, was for Turner "sporage," a good enough word, at any rate better than the Sparrer-grass which has prevailed. Our Turnip Radish, he calls an "Alman or rape radices"—rape corresponding to Brassica Rapa, and not to the B. Napus or Turnip. The latter vegetable was not grown in England at that time; for though Turner says he has "hearde sume cal it in Englishe a

an arber for the tyme of summer." The name Smilax was also applied to the Vew.

The extracts we have made will suffice to show what interest attaches to the "names of herbes," and what service Mr. Britten has done by reprinting it.

Natural History.

ABOUT BIRDS.—It is a matter of regret to all who take an interest in the pursuits of country life and the study of natural history that the opportunities of observing the habits of British birds are restricted, in the case of the majority who have no leisure for extended explorations, to the more common and well-known

preserved neighbourhoods, their numbers were terribly thinned. I wish a Rare Bird Fund could be established for rewarding keepers and others who could point out living specimens in the woodlands in their range, and not let the barn-door be the record of their skill in destroying life. I fear we have but few Watertons left among us—at least, none so bold and outspoken in condemning the cruel warfare waged against many birds of value and interest to the community at large, such as the owl, kestrel, &c. There is some comfort to be found in recent legislative acts which have thrown the eggs of their protection over those birds that are esteemed of benefit, or that do not interfere prejudicially with our crops of corn or fruit. The Wild Birds Protection Acts have been undoubtedly beneficial, but while common birds increase and multiply, the more beautiful and interesting rather show decrease. And one reason, besides the avidity with which they are pursued by collectors and others is, that our rare birds have so few abiding places where they can roost in securely, and find a safe and undisturbed refuge in the nesting season.

It has occurred to me that those naturalists who are strongly in favour of the more complete preservation and protection of rare birds might by joint co-operation give greater effect to the wise and merciful laws recently enacted by imitating the sporting community and establishing coverts for the purpose of securing safe breeding places both for residents and migrants, and providing in such coverts, by the introduction of proper trees and shrubs, a certain amount of natural food, the produce of the plantation. It may seem a little utopian to uninterested people to propose devoting a certain acreage of land merely for the preservation of birds which may not be giving direct benefit to the community; but, properly explained, it is not more so than forming fox-coverts, and maintaining them for the harbour and increase of those animals. If on some of our great estates only one such wood were planted and kept sacred to birds, so fenced that no hare or rabbit or wily fox, or even predatory boy, could invade its guarded precincts, what a source of interest it would become; and it would have the merit of embellishing the landscape, if planted with the following trees and shrubs, all of which afford either food or shelter to nearly every kind of wild bird, always excepting the fen and heath birds. I would plant central groups of the Douglas Fir; this, with masses of Norway Spruce, the Scotch and Austrian Pine, would give shelter to our larger birds, and in time tempt even the banished cross-bill. The Larch should also be included, and the Hemlock Spruce sparingly distributed; the two Cherries, Cerasus Mahaleb and C. Padus, with the Plum, myrobolana and spinosa, Pyrus Malus, Sorbus, and the Mountain Ash—all abundantly; the Elder and Viburnum opulus, Holly; and all these latter, which would be a third rank, should be followed as an outer fringe by Berberis communis and Mahonia, Cotoneaster Simonsi, Leycesteria formosa, the Dog Rose, and the Bramble, with Raspberries and some Gorse bushes, the whole hedged in with the common Thorn, bushes of which should find a place. An enclosure of, say, 4 acres would be insufficient for trees so valuable for birds as the Oak and Beech; the slow growth and unbragous character of these trees would be also against them. The trees named already as suitable would, fairly planted, grow rapidly, and in half a score years present a very fair covert, and would from the second year be valuable for some of the smaller song birds. *William Ingram, Belvoir, February.*

FIG. 42.—SALIX FASTORDIANA: MALE. (SEE P. 298.)

turnepe, and other some a naved or navel [navet, French], yet he mentions it as growing plentifully at Andernake (Andernach) in Germany. Moreover, he tells us that it may also be called "long Rape or navel gentle, as a Rape hath a round roote, so hath a navel a long root and something yealowishe." From this, it is clear that Globe Turnips were not known in those days. Raspberries were clearly not common, for all that is said is that "they growe in certayne gardines of Engleland," less than is said in the case of Savin. What we now call Scarlet Runners were then classed under Smilax hortensis—very wide of the mark, the more remarkable as under the head of Asparagus, as also under Smilax aspera, the writer shows that he knew the true Smilax. Be this as it may, there is no mistaking the author's meaning, for his Smilax hortensis, is a "some wryte, Phascole. It may be called in English kydney beane, because the seede is lyke a kidney or arber beanes, because they serve to couer

forms of bird life. The less frequently met with examples, reported scarce, are becoming really rare. Our local newspapers record with painful iteration the destruction of rare birds, and but too frequently of the seldom seen and interesting Falconidae; only this week I have read of a golden eagle having been shot in Glenalmond, on the Auchnafui Hills. In this neighbourhood several honey buzzards have been cruelly killed. The newspapers recorded the appearance of the little bustard in Cambridgeshire, and their speedy destruction. The bittern is practically extinct in the British Isles. The ruff and reeve, once so common in Lincolnshire, may in many seasons be sought for fruitlessly. Amongst still smaller birds I miss the crossbill, thought it may be found in the great Scottish forests. That handsome bird, the hawfinch, was, prior to the winters of 1880 and 1881 sufficiently numerous in the Belvoir Woods; but, driven by hunger to less

THE WRYNECK.—I heard this bird in Hampshire on February 13 in a small plantation near the roadside, so I trust that the old folklore belief in the wryneck being the advent of a mild, early spring may be confirmed this year, though our spring flowers, such as Primroses, Potentilla, and wood Anemone are very late in showing bloom. *Helan E. Watney, Liss.*

THE SEED HARVEST OF 1881.—Messrs. James Carter & Co., of High Holborn, in a report just issued, state that, with few exceptions, the seed crop of 1881 was superior to that of 1880, both in quantity and quality. The extreme drought of July last, and the succeeding heavy rainfall in August, resulted, however, in a shorter crop of grass and some other seeds than the earlier anticipations warranted.

Orchid Notes and Cleanings.

DENDROBIUMS ON BARE BLOCKS.—In the current number of *The Gardener* Mr. Spyers states that he has cultivated the following species successfully for several years with their roots attached to bare blocks of wood:—*D. aggregatum*, *D. teretifolium*, *D. Jenkinsii*, *D. linguiforme*, *D. chrysotoxum*, *D. suavisimum*, *D. capillipes*, *D. sealei*, and *D. ciliare*. The blocks were in every case used green, with the bark attached, and were cut from such trees as Pear, Maple, Dogwood, Acacia, Box, Thorn, Elm, and Elder. The enormous specimen of *D. chrysotoxum* at Burford Lodge, which yearly produces over fifty spikes, was wired some six years ago to a cylindrical block of Pear-wood. The wood has long since perished, and the roots have penetrated it in all directions, much to the satisfaction of the plant. *D. Falconeri* is another plant that will grow well for years hanging from a block of wood to which the main of its roots are attached.

ODONTOGLOSSUM KOEHLII.—This species is in splendid cultivated condition in the well-assorted collection of David Tod, Esq., Eastwood Park, near Giffnock; in fact, the dozen or so of plants in the collection are quite unique, without a speck to mar the appearance of the leaves. Every leaf is perfect not only as regards the thrip's marks that uniformly prevail, but the extremity of the leaves without a black patch; and the plants, too, are of some size; one beautiful piece I counted had eight young breaks, and the old pseudobulb had leaves 15 to 18 inches long. Many of the bulbs showed four flower-spikes each, and such flowers for size as would delight and astonish even the best-informed orchidophile. All this is brought about in, in the first place, keeping the plants in a warmish temperature; in the second, by a regular process of feeding with well-diluted sheep-droppings, of course cautiously applied; and in the third place, by regular baths of soapstuds from the laundry. I confess I never saw such cultivation of what is acknowledged to be one of the most difficult plants, at least to grow it to any size. It was not a solitary plant, I observe, but the lady, showing the advantages of a good system. Both Mr. Tod and his excellent gardener say that they are the easiest to manage of any group they have. There is no doubt at all that cleanliness is the key to the secret of successful culture; for, no matter how clean and beautiful these plants are, they get their usual soapstuds bath and their usual feed, as a practiced eye can easily detect from the mossy surfacing being in a measure furnished by the ablations. The whole plants in this collection are well handled, and particularly a superb plant of *Odontoglossum Andersonianum*, which has made a growth of Broddingham size, and reflect much credit on the skill of Mr. Ewart, the gardener. *James Anderson, Meadowbank.*

TRICHOPIPLA SUAVIS.—A nice specimen of this lovely Orchid is just now in flower in the collection of D. E. Crawshaw, Esq., Rosedale, Sevenoaks. It bears nearly three dozen of its beautiful spotted flowers, and is a fine Orchid for flowering at this season of the year, especially when done as well as this plant is. *A. O.*

CYPRIPEDIUM BARBATUM.—Mr. Hopkins, The Gardens, High Cross, Framfield, sends us a flower-stem of this Orchid with two good blooms on it, and states that he has a small plant with two flower-stems branched in the same manner.

ORCHIDS AT MESSRS. VEITCH'S.—Amid a profusion of flowers, varieties of *Odontoglossum Cervantesii*, *chibosum*, and *crispum* are remarkable. A fine plant of that good old favourite, *Dendrobium nobile*, grown *au naturel*, is interesting, as showing how the plant grows in a natural state, and how much more impressive it is under such circumstances than when seen as it usually. *Oncidium cucullatum*, with olive sepals and petals and lilac-spotted lip, offers a curious contrast of colours. *Dendrobium Cambodjanum*, with its yellow flowers and dark

brown lip, is remarkable as flowering from the young shoot. Numerous forms of *Cattleya Trianae* are in bloom, one in particular, with flowers of medium size, the sepals and petals transparent white fringed and curled at the edges, and with the lip pale lilac with a yellow disk. *Dendrobium Ainsworthii* is particularly bright with its whitish flowers and lilac lip. *Miltonia cuneata* also, with narrow lilacy-brown sepals and hastate white lip, is noteworthy.

ODONTOGLOSSUM ROSSII MAJUS.—Among the numerous varieties of this useful Orchid now in bloom at Messrs. Veitch's there is one that is remarkable, not only for the large size of its flowers, but for the lilac flush of the sepals and petals, the veins of which are picked out with deeper lilac.

AEKIDES CYLINDRICUM.—A small plant of this is now in bloom at Mr. Williams' Holloway nurseries. The plant has long cylindrical leaves, like those of *Vanda terebinthifolia*, and pure white flowers, the segments being waved and crisped at the margin, the lip projecting into a large funnel-shaped spur, and the column of a slightly rose-coloured hue. It was illustrated in our columns in 1875, vol. iii., p. 537, from a plant in Lord Lonsborough's collection.

ODONTOGLOSSUM PARDUNUM.—Flowering specimens of this may now be seen in the Victoria Nurseries, Holloway. The flowers are in racemes, and have narrow pointed segments of a mustard-yellow colour, the lip being hastate-lanceolate, mustard-yellow, with brown spots.

ODONTOGLOSSUM CRISPUM.—It has been asserted that the varieties lately imported are not so fine as those which were introduced some years ago. We hardly think that those who are in the habit of looking round the London nurseries will agree to this statement. Good and bad varieties are imported now as then. Moreover, our taste has grown more critical. What would have been thought a good variety then, now-a-days would be but moderately esteemed. Of more interest is the alleged fact that each district has, as it were, its own varieties, some parts of the country furnishing much finer varieties than others, so that if the collector get into the wrong part of the country his despatch is likely to be of inferior quality. This phenomenon of local variation is very interesting from a scientific point of view, though not always equally so from that of commerce.

ONCIDIUM LINGUIFORME.—This is a very singular species, not often seen in cultivation, although it was introduced from Meila so long ago as 1840. It succeeds in a cool-house temperature, and makes very strong vigorous growth potted as one would a strong plant of *Odontoglossum crispum*. The singular butterfly-like flowers, of a yellowish-brown colour, the lateral sepals tipped with yellow, are very thinly placed on spikes from 9 to 12 feet long. It should be in every large collection of Orchids, and it may now be seen in capital condition in Messrs. Veitch's nursery at Chelsea.

CATLEYA AMETHYSTOGLOSSA.—A distinct and very beautiful species, of which there are two fine forms in flower in Messrs. Veitch's nursery. Like *C. Leopoldii* it is a Brazilian species, producing its flowers on long stems furnished with two leaves at the top, from between which the spikes of flowers issue. It is very desirable for winter flowering. The sepals and petals are pale purplish rose, irregularly spotted with purple, the lip deep purplish-crimson. It succeeds very well potted in turfy peat and sphagnum, like other *Cattleyas*; and, like *Cattleya Mossiae*, there are many distinct forms of it found amongst imported plants.

DENDROBIUM JAMESIANUM and *D. INFUNDIBULUM* are grown in the Mexican-house at Burford Lodge. Many good growers had arrived at the conclusion that these two fine species would succeed best in the cool-house with *Odontoglossum*. At many first-class establishments we have seen them do well with the coolest treatment. We noticed that Mr. Spyers had placed his plants at the coolest end of the Mexican-house, where they had made splendid growths, which were fast becoming studded with flower-buds. Most of them are grown in pots, but there was one very fine large plant on a block doing equally well.

The Kitchen Garden.

WHERE new plantations of *Asparagus* are contemplated the ground should, if not already done, be got ready for planting the roots next month; it should be deeply trenched, and a liberal supply of well-rotted manure be incorporated with the soil as the trenching proceeds—should there be a uniform depth of soil, 3 feet at least, and if it be of a sandy alluvial nature, and impregnated with saline matters, it will in every respect, providing the drainage is good, be suitable for the growth of *Asparagus*. Existing beds should without further delay have the short dung that was laid on them last autumn carefully forked in, so as not to injure the crowns in the operation, and the soil broken fine with the fork as the work proceeds. The beds should then be lined off afresh, and a few inches of soil from the alleys laid on, which, after a few days' exposure to the weather, and when sufficiently dry should be raked over; and where leaf-mould is plentiful a few inches thick might then be put on the beds. This, in my opinion, causes the "grass" to come more crisp and of a better colour. Seed-beds and seedlings just coming through the surface of the bed will require being protected, with a piece of netting supported by short sticks, from the ravages of chafinches and sparrows.

Small sowings may now be made in a warm border of the following seeds:—Early London Cauliflower, Snow's Winter White Broccoli, Cottagers' and Scotch Kale, and a good breadth of Curled Parsley. Make another sowing of Broad Beans and Peas, and draw a little soil up to those sown at the end of December, and stick the latter forthwith. Old Cabbage stumps should be removed at once, and the ground be made ready for Potatoes, of which a small planting of the early kidneys may be made forthwith in rows, 25 feet apart, and 10 or 12 inches in the row, between which Cauliflowers will be planted next month. It will be advisable to defer planting the main garden crop of Potatoes a couple of weeks longer with a view to their escaping late frosts, in the event of there being any. If the ground, having been heavily manured for the preceding crop, is moderately rank, it will be unnecessary to manure it for the Potato crop; indeed, the latter, under the circumstances, will be better in a quality and quantity without it. Early plantings of Cauliflowers and Cabbages should, if not already done, have the Spruce boughs with which the plants have been protected removed and the latter earthed up, the blanks, if any, having been previously filled up. Make fresh plantations of Jerusalem Artichokes in a good open piece of ground in rows 2 feet apart and 1 foot asunder in the row. See that the Dutch hoe is used freely between the rows of Lettuce, autumn-sown Onions, Spinach, &c., not only as a means of keeping down weeds, but also to accelerate growth in the plants through the stirring of the soil.

FORCING DEPARTMENT.—See that the supplies of *Asparagus*, *Seakale*, and *Rhubarb* are equal to the demand, and that pits and frames in which Potatoes and Carrots are growing have sufficient air admitted to them to prevent the plants making a spindly growth; the former, however, must be regulated in accordance with the nature of the latter and the condition of the weather, which latter being favourable the sashes should be taken off advanced crops of Potatoes early in the morning and replaced late in the afternoon. French Beans, where grown in early vineries and Peach-houses, will require extra attention in the application of water both to the roots and overhead, otherwise red-spider will be sure to attack the plants. Sufficient batches of seed should be planted at frequent intervals to maintain a good supply. Top-dress succession crops when about three inches above the rim of the pots with soil similar to that in which the plants are growing, and from which the chill has been taken off; and pinch the points of the shoots out to make them branch. Young plants of Brussels Sprouts, Cauliflower, Lettuce, and Leeks should be picked out in a frame with a gentle bottom-heat as soon as large enough to handle, preparatory to being planted in the open later on. Sow Moore's

Cream Vegetable Marrow and Stockbridge Ridge Cucumber seed, and when large enough pot singly, the latter in 48's and the former in large 60's; a sowing should also be made of red and white Celery of the varieties most approved of in individual establishments—Turner's Incomparable White and Cole's Red Defiance, or Leicester Red, are excellent varieties of the respective kinds. *H. W. Ward, Longford Castle Gardens, Wilts.*

ONION SOWING.—Whether it be the right time or not to sow Onions during February, I have endeavoured for many years to have the seed in the ground as soon after the middle of February as circumstances would allow. This year the main sowing (not a small one for a private place) was covered in, the ground all rolled and finished, on February 14. I have practised this in five counties in England, and in one cold northern district; I do not remember sowing later than February, and the crop never was second-rate. At the present time our soil is of the heaviest kind; the bulbs grown thereon are of great size, and keep well. *K.*

NOTES ON VEGETABLES.

PURPLE SPROUTING BROCCOLI.—The mildness of the weather has been much in favour of vegetables all through the past winter season, during the whole of which time there has been an abundant supply, and the old Purple Sprouting Broccoli has quite maintained its high character as being one of the best and most productive things in the garden. Not only do plants of it yield an enormous quantity of sprouts, but these latter are, when cooked, simply delicious—far superior in tenderness and delicacy to any other Broccoli grown; that is, when the Sprouts have escaped frost, which detracts from their flavour. To have fine large plants—and it is only these that are profitable—the seed must be sown not later than the middle of March, and as soon as the plants are large enough to handle they should at once be pricked out in light rich soil, at about 6 inches apart. This will prevent the stems elongating, as they always do in beds, and the removal will greatly increase the number of fibrous roots, and render the plants more fit for transplanting when ground becomes vacant. Like all the Brassica tribe Sprouting Broccoli are gross feeders, and require deep rich land, where they should be planted 2 feet 6 inches apart; or, better still, double that distance, with a row of Potatoes between. With such an increase of room they form huge bushes, and the amount of food they afford is something surprising, as they continue to branch and sprout for a very long period. *J. S.*

ALGURTH BRUSSELS SPROUTS.—As the season for sowing these is at hand I should like to say a few words in favour of the strain known as the Algurth, which are a great improvement on the old imported kind, as they bear large compact solid sprouts that are of fine flavour when cooked. To have Brussels Sprouts at their best they require a long season's growth, and it is advisable to sow under glass early in March, and prick the plants out, that they may be sturdy and strong for the final removal. If thinly planted, at wide distances apart, so as to allow plenty of room, they form huge stems a yard high full of sprouts, large in proportion. Plants from late-sown beds are comparatively useless, and the more so if they receive a check or become drawn, after which they rarely make much progress, but remain stunted and poor. At one time gardeners would not think of sowing other than imported seed, but were selections to be made of the best among plantations of Brussels Sprouts there is no doubt but that we should soon have them greatly improved, as among a number of plants they vary much, and seed should only be saved from those showing distinctness of character. This is the plan pursued by market gardeners, who generally have good types of Brussels Sprouts and Cabbage, which may be seen at a glance by the regularity of their growth and general appearance. *J. S.*

EARLY FLOWERING SHRUBS.—In the early part of February we had no less than twelve shrubs in flower in and near our garden in West Sussex; the wild Gorse and a few flowers of Arbutus would add to the number—*Andromeda floribunda*, *Berberis japonica*, *Chimonanthus fragrans*, *Erica carnea*, *E. codonodes*, *Garrya elliptica*, *Jasminum nudiflorum*, *Kerria japonica*, *Lonicera Standishii*, *Prunus californica*, *Vyrus japonica*, and *Viburnum tinus*. *H. K.*

Plants and their Culture.

STOVE FLOWERING PLANTS.—Under the ordinary treatment of the stove, *Gardenia intermedia* is now rapidly swelling its first flower-buds. If the plants are well rooted liberal supplies of liquid-manure will greatly aid them in the development of the blossoms. These, when cut from the plant, will look far better if a few inches of growth can be spared also; nothing looks so harmonious so well with these flowers as their own foliage. Plants of *Allamandas*, *Clerodendrons*, and *Bougainvilleas* that have been started early will now be breaking freely. Keep them elevated as near the glass as possible, in order to obtain a sturdy, short-jointed growth. Plants of the shrubby *Clerodendrons*, as *Kæmpferi* and *fallax*, should be pruned into the hard wood, then shaken out and repotted into smaller sized pots; they want, in fact, about the treatment generally given to show *Pelargoniums*. They are grand subjects for the stove during the autumn. The stove *Vincas* will do well treated in a similar manner, keeping them constantly pinched at about the third joint until a bushy plant is formed. *Rondeletia speciosa* and the major form will always make more shapely plants if they are annually pruned in to the hard wood. It is a great mistake to grow these handsome flowering plants as climbers, in which manner they never flower so well. Where they are grown the pruning should not be deferred any longer. Pinch them once during the month of May, a regular break will then be secured; nearly every shoot will during the autumn produce a truss of flowers under this mode of culture. *Isoras* may also be treated in a similar manner; but I should prefer in the case of these to grow on young plants and discard the oldest ones. *I. coccinea* is still one of the very best all-round varieties, no kind surpasses it for cut purposes. The young growths of *Dipladenias* should be trained on string or wires near the glass. On no account should the young shoots of these handsome flowering plants be constantly tied in to the trellis until a good crop of flower-spikes are well forward. Of plants suitable for growing in suspended baskets in the stove, the *Jischyranthus* in varieties and *Hoya bella* are among the best; young plants of these should be made up in the baskets, if it is convenient to grow them in this manner, as soon as possible, and a good season's growth will then be obtained. The *Epiphyllums* also do well under this mode of treatment. Of plants not generally grown in our stoves, *Mussaenda frondosa* is very singular and pleasing, so is *Dalechampia Roedliana rosea*, both with singular bracts. *Medinilla magnifica* is one of the grandest stove flowers; treat young plants of this liberally and give them plenty of room. The flowering panicles of this plant will soon appear, when this is the case water more freely. Where several plants of *Anthurium Scherzerianum* are grown, part of the stock may with advantage be retarded in a temperate house. Cuttings of *Eranthemum Andersoni* struck now will make nice flowering stuff during the autumn. Seeds should also sown of *Aphelandra aurantiaca Roedlii*, *Torenia Baillonii*, and *Fournieri*—the former to flower next winter, the two latter during the summer and early autumn. Attend to the general treatment of the stove as previously advised; slightly increase the day and night temperatures if any necessity for so doing should occur, otherwise it will be best not to rise too rapidly for a few weeks to come.

GREENHOUSE.—Beyond the ordinary routine of this department there is not much pressing work at present. All kinds of hard-wooded Cape and New Holland plants will require close attention for watering; any that are developing flower-buds must not be allowed to go too far on the dry side now, or crippled and ill-formed flowers will be the consequence—with Heaths in particular. Plants of winter-flowering Heaths and *Epacis* should be cut back and induced to break into fresh growth at once. *Pelargoniums* for the latest flowering may be pinched once more; all the stock should have the growth tied out somewhat if good plants are desired. The latest *Cinerarias* should soon be removed to a cold pit, watching, however, for any frost. With this mild weather *Chrysan-*

themums will be starting off rather freely; keep them well aired on all favourable occasions in order to keep them as sturdy as possible.

CONSERVATORY.—The *Camellias* will now be making a good display; plants now in full flower must be watered freely. What with the bulbs and forced plants there is no lack of flower to make a good show; do not, therefore, let anything remain when much past its best. Nothing detracts more from a good floral display than the oversight of not removing stale and decaying flowers. Young hands should also exercise their ingenuity in producing an effective grouping, varying the same as much as possible. *James Hudson, Gunnersbury House, W.*

Peaches and Nectarines.

THE fruit in the early house will now have commenced stoning, during which time the night temperature already given (from 55° to 60°) will be quite high enough. It is much the best to err on the safe side rather than to keep a high night temperature and lose a quantity of fruit during the stoning period, keep a chink of air on "the front" as well as the back ventilators all night, and carry out the directions given in last Calendar as to tying down, &c. The third house will now have set its fruit, and may be gently syringed with tepid water twice daily, and will also require disbanding. I make a practice of doing a little of this daily. I never encourage spurs, as I have always found the best fruit produced on young well-ripened wood. If the trees in this house have not been watered since they came into bloom, they may now have a thorough soaking of tepid water. The fourth house will be in bloom and fertilising must be continually attended to. Late houses are coming on fast, and will soon be in bloom (if the mild weather continues), in spite of ventilators being kept open to the fullest extent night and day. *J. Wallis, Keele Gardens.*

The Hardy Fruit Garden.

PROTECTING FRUIT BLOSSOMS.—The buds of Apricots, Peaches and Nectarines are now getting very forward, and the chances are that without good protection the blossoms will get cut off, as, judging from present appearances, they must be open at latest by the second week in March, when we may have cold winds and frosts too cutting for them to withstand. For protection by day I place great reliance on old fish-nets, such as are used for preserving fruits from the attacks of birds, which, put on double, so as to bring the meshes across each other, sift the wind and take from it its sting. What injures the flowers of Apricots and Peaches, perhaps, more than anything else is wet, which is more fatal than cold, as it is surprising what an amount of this blossoms will stand on which rain cannot fall. With a coping, and a double net in front strained straight down, rain will pelt in vain, as the drops dash against the coping and are broken up and fall quickly down to the earth; and the same with snow and hail, which are intercepted in their course, and lodge where they cannot do harm. Wood copings are better than nothing, but glass copings are the thing, as they do not obstruct the light, and the trees can therefore set the whole of their flowers right up to the top. As to the injury they do by keeping out the night dews, &c., that is more imaginary than real, and I found ours of the greatest use last summer in protecting the fruit of the Apricots from wet, which saved them from rotting. This was strikingly proved with us, as we had one wall without coping, and the fruit on this, as is common with Apricots, spotted and decayed so after showers or damp nights that we had a difficulty in finding any fit for dessert. In contrast to these those on the walls with the coping, and growing on the same aspect, were fine and sound, and ripened splendidly; and it was the same with our Wallburton and other late Peaches. The material we are using for blinds is a striped thick Forar, which we get at the draper's at 5s. per yard. The width of it is a little over 4 feet; so that for £2 15s. or so we have enough for a wall 150 feet long. The material is so thick and strong in the thread that it will last for years if stored up and kept dry. *J. Sheppard.*

THURSDAY, Mar. 9	Rooms	Sale of Imported Orchids, at Stevens'
SATURDAY, Mar. 11	Rooms	Sale of Hardy Plants and Bulbs, at Stevens'

It may seem early to write of FRUIT PROSPECTS, still it is already possible to read the state of the buds, and to tell whether or not there are any, and how many, fruit ones among them. It is pleasing to be able thus to note that fruit buds are a full average crop, Plums promising more than an average. Neither are fruit buds generally much earlier than usual. The wet autumn, dull winter, and few occasional frosts have held fruit buds back almost as effectually as the usual severities of our normal winters. The abnormal mildness of the winter seems so far to have expended its chief forcing powers on Roses rather than fruit trees. The former apparently intend, present weather continuing, to bloom in April or May rather than June—the latter to open their flowers about the usual time.

Of course the entire character of our fruit crop will turn on the time of blooming, the character of the weather at that particular crisis, and the means of assistance in the shape of protection we can give to the trees. Be the weather what it may, the blooming season cannot be much longer deferred. Apricots mostly bloom in March; Peaches, Plums, Pears early in April; Apples in April and May. As a rule, the later the blooming the more sure the setting. February has done comparatively little to its proverbial ditch filling this year, consequently the ground is drier than usual; hence March sunshine is likely to exert its full power in drawing out the bloom, unless its influence is counteracted by biting winds and stinging frosts. With fairly seasonable weather our prospects are promising. But should the winter weather that we have as yet steered clear of come upon us during the next three months, a full fruit basket can hardly be one of the welcome and pleasing gifts of 1882.

This suggests questions of what can be done to protect our fruit crops from inclement weather should it come, as is all too probable. Some affirm nothing is gained by our help. There may be this grain of truth in such sweeping assertions, viz., that over-protection is often far worse than none. Still it remains true, that judicious protection saves many a crop that would otherwise be wrecked by the weather. This being so, it is surprising that more protective expedients are not employed—the more so as they are generally successful in the exact ratio of their simplicity. A handful of bracken, a wisp of straw, an old newspaper, a roll of Frigi-domo, old fish-net, bunting or canvas, a screen of boughs or of furze—these prove among the most potent of all fruit blossom protectors. The more ponderous the more injurious; the more flimsy, light and mobile, the more efficient. This being so, the chief problem is to ensure sufficient stability against winds and enough resistance to frost without ponderous expensive expedients, or doing more mischief by our shade than we do good by our protection.

It should, however, be borne in mind that all shade in the spring is not only and wholly evil; on the contrary, we may retard as much by our shade as we shelter by our artificial husbanders of warmth. Hence the cheapest as well as the most efficient protectors are probably those that are permanent. They act with double force, and it is doubtful whether their holding back of the blossoms does not save as many of them as their keeping of them warm.

Loose straw bands, but for their litter-making,

are excellent protectors, and so is paper of all sorts, as long as it can be kept dry. The efficiency of woollen and most other nets is well known. Open as these are, they are safer, and probably, as a rule, even more efficient than bunting, canvas, and other close textile fabrics. A thin thatch of dead bracken fronds is a perfect screen, virtually weather-proof—a true regulator and mediator between extremes, shutting out the fierce warm beams of the sun as effectually, when these would prove mischievous, as it shuts in the heat, when all is too little to moderate the extreme energy of radiation from the tree or wall surfaces during clear frosty nights. The flimsiness and mobility of the gossamer-like dry Fern fronds all aid its protective power and help to make it more efficient. A screen of Spruce or other boughs is ponderous, clumsy, and inefficient compared to one of bracken. Asparagus tops cut before they are dead ripe, carefully dried and stored in bundles without being severely crushed, form an equally good though hardly so durable a screen. They are so brittle as to be practically useless unless harvested before they are quite ripe. It is the little juice left in them that imparts sufficient toughness for protective purposes.

Such substances as Raffia-grass, could it be had sufficiently cheap and in plenty, would also form a capital screen, as would some of the lighter Rushes, Reeds, and grasses, if carefully harvested. Most of the canvases, buntings, &c., specially manufactured for these purposes are too smooth. Flimsiness, fluffiness, combined with sufficient strength to make them durable, and enough thickness to afford sufficient resistance to 10° or 15° of frost, are the qualities desiderated as protectors for fruit tree blossoms; and only those that have tried such screens as are here commended will believe that they have proved generally able to save the crops without injuring or weakening the trees, or fostering the increase, or enlarging the destructive powers, of those insect pests which seem ever ready, lying in wait to wreck or ruin any fruit blossoms that the biting frosts and blasting winds may have left.

— STREPTOCARPUS GREENII. — This plant is the result of a cross between *S. Saundersii* and *S. Rexii*, *S. Saundersii* being the seed-bearing plant. The plant is much more compact and dwarfer than *S. Saundersii*. Mr. GREEN tells us that he grew a quantity for several years among other cool greenhouse plants, and found it very useful. The plant is very easily grown: first sow the seed in a pan of light sandy loam, then prick off or pot singly in very small pots, place them afterwards on a shelf as near the glass as possible, shade for a few days, after which they will bear the same treatment as *S. Rexii* with ordinary greenhouse plants.

— ROYAL HORTICULTURAL SOCIETY. — The Council announce an Implement Exhibition, and a general display of garden structures, tools and appliances, which will be held in the gardens at South Kensington from May 23 to July 5, 1882, comprehending the four great events of the season, viz.:—The Great Summer Show; the Evening *Fete*; the Pelargonium Society's Show, and the Grand National Rose Show. Increased facilities and accommodation are offered to exhibitors, and silver and bronze medals will be awarded for the best articles exhibited in the following classes:—Modes of heating a small conservatory attached to a dwelling; Eoliers heating 50 feet of 4-inch piping with or without brickwork; Hot-water piping: modes of fixing and fitting the same, valves, &c.; Plant-house, vinery or orchard-house, span-roofed or otherwise, not exceeding 50 feet in length; Movable plant pits or frames; Improvements in glazing, ventilation, &c.; Decorations for conservatories, ornamental flooring, flower stands, vases, &c.; Hand mowers; Horse mowing machines, to cut not less than 30 inches; Wirework; Garden pottery, edging tiles, &c.; Garden seats, chairs, &c.; Garden engines, syringes, &c.; Garden tenting, shading materials, &c.; Complete set of lawn tennis apparatus; Miscellaneous subjects not included in

any of the classes; Garden cutlery; Garden tools, spades, rakes, hoes, barrows, &c.; Meteorological instruments; Plant guards and supports, flower stakes, labels, &c.

— THE GREAT WHITSUNTIME EXHIBITION AT MANCHESTER. — We have received a copy of the schedule of prizes offered for competition at the Annual Grand National Horticultural Exhibition to be held at Manchester from May 26 to June 2. There are seventy-seven classes in all, one being open, forty-five confined to amateurs, and the remainder to nurserymen. As usual the prizes offered are very liberal, and, as usual also, there can be no doubt, the show will be worthy of Mr. FINDLAY'S efforts.

— EPACRIS ONOSMEFLORA. — A good many of the true species both of *Heaths* and *Epacris*, so deservedly popular a generation or so ago, seem to have become lost to cultivation. This is all the more to be regretted, as many of them vie in beauty with the productions of the hybridiser's art. The attention bestowed on the hybrids now so widely grown seems to have caused Nature's wildlings to be neglected and forgotten. A very pretty species of *Epacris*, *E. onosmeflora*, is now in flower at Kew. It is an interesting and very floriferous plant, with compact bushy habit, and short, broadly tubular white blossoms. It was sent to Kew at the close of the first quarter of the present century by A. CUNNINGHAM, who discovered it in peaty bogs on the Blue Mountains of Australia, at an elevation of 3,100 feet above sea-level.

— THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY. — At the annual meeting of this Society, recently held, a very satisfactory report and statement of accounts was presented, showing the Society to be in a very solvent state, with a good surplus to the fore. The Treasurer's balance-sheet shows that the Society has now invested in the Bank of England in 3 per cent. Consols the sum of £2161 12s. 6d.; the number of members has materially increased during the past few years, and constant additions are being made. As the principles on which this Society are founded are not generally known, it may be remarked that a man must be a gardener when he joins it, but should he leave the gardening profession and follow some other occupation he does not lose his connection with the Society. It is a provident society in every sense of the word, differing from that in operation in relation to the Foresters and Oddfellows in that there is no burial fund. There are two scales of payment to the benevolent fund—one of 6d. per week, and the members who subscribe that sum receive 10s. 6d. per week in illness; and a larger sum of 9d. per week entitles the member to 16s. per week in illness. Members who do not subscribe to the benefit fund, but who may meet with an accident and are disabled from work for a time, receive a sum of money from the committee out of the benevolent fund. The good health of the members is shown from the fact that during 1881 the sum of £111s. 6d. only was paid as sick pay. The Secretary of the Society is Mr. JOHN McELROY, The Gardens, Moray Lodge, Campden Hill, Kensington, W., who will gladly supply particulars and copies of the rules of the Society to gardeners.

— MESSRS. VEITCH'S AMARYLLIS. — We have already alluded to the fine collection of these very showy plants raised by Messrs. VEITCH (p. 257). We allude to them again to advise those of our readers interested in these noble plants to pay an early visit to Messrs. VEITCH'S, as fresh flowers of extraordinary richness of colour are expanding daily. Not only in colour, but in form and substance, great advance is being made, but, as usually happens, there is a tendency to run too much in one groove and produce a uniformity of form which, though pleasing to the specialist, would be more interesting to the ordinary lover of plants if more varied. In any case, we can but congratulate Messrs. VEITCH on the acquisition of so fine a strain.

— ROOT FORMATION. — Mr. BAINES sends us a mass of thick, fleshy roots of a *Pavia*, each about the thickness of the little finger, contorted and intertwined in all directions so as to form a globular mass. Four years ago, in order to prepare the trees for removal, the roots were cut through at a depth of 2 feet 6 inches beneath the surface, the result being the formation of a leath of fibrous roots, which either

FIG. 43.—STREPTOCARPUS GREENII: HALF NATURAL SIZE: FLOWERS PALE LILAC-BLUE. (SEE P. 302.)

met with some obstacle, or became so intertwined that they obstructed each other; in any case, they now form a ball of thick and twisted roots, as before said. Microscopic examination shows a thick corky rind of several layers of brown cells, the innermost forming a growing layer, or phellogen. Within this is a thick, spongy mass of ordinary cellular tissue, which, in its turn, surrounds a narrow continuous ring of woody and vascular tissue, while in the centre is more cellular tissue, forming the pith. In the normal fully developed root the wood zone occupies nearly the whole of the diameter of the root, so that in the abnormal specimen there is a great development of spongy cellular tissue, while the woody portion is relatively small. On cutting through the mass it may be seen that one of the smaller original roots, which is rather more than the thickness of the thumb where cut across, split into a Λ -shaped fork after the injury.

— RAILWAYS AND MARKET GROWERS.—The London and North-Western Railway managers have just made public an arrangement by which it is proposed to receive at Kew Bridge station loads of garden produce which will be delivered at Manchester, Liverpool, and other great centres of population in the North, early next morning. That there are at times far more of market vegetables grown around the metropolis than can be profitably disposed of there can be no doubt; but whether it will pay growers to send loads of vegetables and fruit 200 miles, and then find a salesman to dispose of it, is not so certain. A few ventures will soon dispel whatever doubt may be attached to them. No doubt it seems odd thus to find encouragement given to the sending of garden products away from London, but it is not exactly a case of sending coals to Newcastle. Lancashire has an enormous population, and it may be that it will gladly take at a remunerative price all those garden products which London does not need or cannot afford to purchase.

— ROCK GARDEN AT KEW.—An official response has been received to the memorial recently presented to the First Commissioner of Her Majesty's Works, &c., in which it is stated that "a rock garden is now in course of formation in the Royal Gardens, Kew." We congratulate the memorialists on the success of their endeavours so far, and trust, as indeed we have reason to do, that, in due time we may witness a rock garden worthy of the Royal Gardens—a source of gratification to the visitors, and a great addition to the means of scientific observation and research.

— SEEDLING RHODODENDRON.—Messrs. VEITCH have now in bloom for the first time a very beautiful new Rhododendron, which appears to us to be distinct in colour from anything yet seen. It is a cross between Duchess of Edinburgh as the pollen parent and *R. javanicum* as the seed parent. The truss contains ten or a dozen somewhat funnel-shaped flowers with a flat limb divided into fine rounded lobes of good form and substance and of a refined though brilliant colour which may be described as orange-scarlet suffused with crimson, and with a faint narrow edge of carmine. The anthers are of a deep carmine colour. If the habit should prove good this unnamed seedling will prove a great acquisition. Maiden's Blush is also in flower, the blossoms being of a pale flesh tint, of great solidity and substance and excellent form.

— ERICA HERBACEA.—This species, which is perhaps better known under the name of *E. carnea*, and is represented in cultivation by white, purplish, and flesh-coloured varieties, is one of the most desirable of early spring-flowering plants. A figure of the flesh-coloured form is given in the first volume of the *Botanical Magazine* (tab. II) nearly a century ago. It is a native of South Europe but quite hardy in this country. CURTIS, in the book just mentioned, speaks of the species as a modern introduction, and states that it may be had in flower "as early as March, especially if kept in a greenhouse or common hotbed frame, which is the more usual practice." At the present time this pretty Heath is in full flower in many gardens, indeed in mild winters like the present one it commences to bloom in the open borders in January.

— FRITILLARIA SEWERZOWI.—In the letter-press accompanying the figure in a recent volume of the *Botanical Magazine*, Mr. BAKER speaks of this as

"one of the most curious—I would not say beautiful—of the many new bulbous plants that have rewarded the recent enterprising and assiduous researches of the Russian naturalists in Central Asia." It differs a good deal from the ordinary Fritillaries by its very distinct habit—the long raceme of funtesselated flowers, lurid purple outside, and the largely developed leafy bracts. This species is quite hardy, and is now flowering in the herbaceous department at Kew. It is a native of the mountains of Turkestan, reaching an elevation of about 6000 feet above sea-level.

— CATALOGUE OF POTATOS.—Mr. SHIRLEY HIBBERD has published in the last number of the *Gardener's Magazine* a list of 540 so-called varieties of Potatos, 140 of which are considered as synonyms. Indications are given as to the Form—kidneys or rounds; Colour—mottled, purple, red, or white; Size—large, medium, or small; Quality—excellent, second-rate, inferior; Productiveness—first-class, second-class, third-class; Height—tall, medium, or dwarf; Season—early, medium, or late. Accompanying the list are sundry articles on the dietetic value of the Potato, and its culture for exhibition purposes and otherwise. The list will be of such permanent value for reference that the thanks of all concerned are due to Mr. HIBBERD for this fresh example of his labour and patience.

— THE SINGLE BLUE ROMAN HYACINTH.—Under this name Mr. ROBERTS is growing at Gunnersbury Park a single blue variety that is much larger and later than the white Roman Hyacinth, and which is no doubt one of the Paris or Italian Hyacinths, and which some twenty years ago were known to the London trade as Belgian Hyacinths. When placed several bulbs in a pot it blooms freely; the spikes of bloom, which in point of size may be regarded as intermediate between the Roman and the ordinary Hyacinths, are very useful in a cut state. Mr. ROBERTS speaks very highly of it, and regards it as of great service to gardeners. But it is misleading to term it a Roman Hyacinth, as those who obtain it in the belief that it will bloom as early as the ordinary white Roman Hyacinth will be disappointed. Still it is a useful type, because coming into bloom between the latter and the ordinary forced Hyacinths.

— CHIONODONA LUCILLE.—This pretty spring-flowering plant promises to realise all the expectations formed of it, excepting perhaps in that it will scarcely be freer of bloom than *Scilla sibirica*. If a few bulbs be put in a pot, and brought on in a cold frame, they bloom freely, and are found by gardeners very useful to cut from. Mr. ROBERTS is growing a quantity at Gunnersbury Park in this way, and one good quality possessed by the plant is the comparatively short time after planting in which the plants come into flower. No doubt when it becomes well established in the open ground it will bloom much more freely than when grown in pots as fresh-planted bulbs, but it will be advisable to place a hand-light over a clump, to keep the flowers from harm, if it is intended to cut them for indoor use. It appears to be a plant that makes rapid increase, and it will no doubt soon become quite plentiful in gardens.

— A MINIATURE FIRE ANNIHILATOR.—A trial of a new and decidedly novel fire extermiator was carried out the other day in the nursery grounds of Messrs. JAS. CARTER & Co., at Forest Hill. That the test might be a severe one, a large pile of wood of the most combustible kind, flour barrels, bulb cases and similar material, had been broken up and piled into a heap some 8 feet in length, 3 feet in thickness, and about 6 feet in height. Still further, a quantity of tar had been thrown over the heap, so that it was likely to burn as furiously as could be desired. The extermiator is known as STRONG'S Patent, and has a pneumatic adaptation applied to it in the shape of an air-pump. It consists of an iron cylinder some 2½ feet high and about 10 inches in diameter, and holds 6 gallons of water; but it is the rule to put in about 5 gallons, so that ample room is left on the top for the compressed air which is forced into the cylinder by means of a small air-pump fitted to the side of the cylinder, and a small pipe inside conducts the air to the surface of the water. On the top of the cylinder is an indicator which tells exactly the internal pressure up to 100 lb. the square inch. It requires four minutes pumping to reach this point. When thus charged—as was the case several

times at the trial in question—the body of wood was set on fire, and then was allowed five minutes' start. Owing to the combustible nature of the material the whole pile was soon in a perfect mass of flame. Mr. STRONG, who was present, then had the cylinder lifted on his back, where, secured by shoulder-straps, it was carried with ease, and holding the small brass nozzle attached to flexible tubing, and which is fixed to the bottom of the can—turning the tap the stream of water, which was about the size of the stem of a clay tobacco-pipe, was driven against the flame with a astonishing force, and one side of the heap was cleared of all flame in a trice, that quite surprised the onlookers. The same result followed as quickly when the other sides and the ends were played upon, and for all practical purposes the fire was fully mastered in about four minutes. It was then agreed that the mass should burn so far as to fall into a solid heap; and in the meantime the cylinder was re-charged with clear water and compressed air; then, at a given time, the water was again turned on to the heap, then all ablaze, and in a few moments all flame was extinguished. Another and smaller wood fire, about 4 feet square and height, was then lit, and this having become a mass of flame was entirely extinguished in three minutes, and being allowed to re-burn, was again extinguished in the same time. A large quantity of tar spread on the ground and surfaced with paraffin was then set on fire, and instantly was a mass of flame, about 8 feet long and 12 inches wide. This was quite put out in four seconds—so to speak, instantaneously, and the most entire satisfaction was shown with the result. The real value of this patent would be found if one of the cans were on hand and fully charged, as they always can be, when a fire breaks out. It is not the volume of the water which is so potent, but the force with which it is projected, and which literally beats down the flame in a few moments. The pressure is strong enough to throw the water 30 feet into the air, and 40 feet laterally. As the can is thus carried on the back and the water is propelled with such regular force, the operator has but to give his entire attention to extinguishing the flames. Apart from the singular power thus evinced, the patent might be found exceedingly serviceable in cleansing wall trees, Roses, &c., of aphids, for no insects could withstand the force of the jet, which can be concentrated in one small stream, or be spread over a wider area. Amateur rosarians would probably find the patent of great use to them; and, indeed, for the washing of windows and glasshouses it would be of considerable service. Still, their primary object should render these pneumatic cylinders of great interest to all.

— COLOUR AT THE TIPS OF THE LEAVES OF HYACINTHS.—Mr. BURRIDGE sends leaves of Hyacinths marked at the tips with broad coloured spaces, pink or blue, in accordance with the colour of the flowers. The circumstance is not unusual—it is the extent of it alone which is remarkable. The arrangement of colour (other than green or that yellow tint which arises from the absence of leaf-green, chlorophyll) seems often, but not always, to be associated with relative arrest of growth: thus the tips of Hyacinth leaves once formed cease to grow, any further growth that ensues takes place at the base. Compare again the petals of a flower with a leaf: in the first case growth is arrested much sooner than in a leaf; so also the seed-coat, which soon stops growing, is often brightly coloured. The fact that the tips of the flower-segments in Hyacinths are often green does not materially invalidate our statement, for the apical growth is soon arrested. The tunic of a bulb when coloured, the skin of a purple-tubercled Potato are other instances in point; note also the brilliant bud scales of some of the Rhododendrons which have but a limited growth, and compare them with the green leaves of the same plant. If you would get colour into the leaves of the Ice-coloured Pelargoniums you put them close to the glass where, owing to the action of light, actual growth becomes checked, though the material for future growth is obtained. All these instances seem to point to a co-relation between arrested or intermittent growth and the development of colour. On the other hand, where growth is rapid and continuous, colour, other than green, is likely to be deficient.

— BOTANICAL NOMENCLATURE.—Mr. BATTEN raises a question in the *Journal of Botany* as to the advisability or otherwise of rigorously confining to

an established botanical rule in virtue of which an author affixes his name or his initials as the authority for the species of which he is the first to publish an account, although it may be that some one else has preceded him with an unpublished name in the form of some manuscript note inscribed on a herbarium sheet or otherwise. Strictly speaking, no doubt if WHITE describes a new species for the first time, he is entitled to put his name to it, as vouching for the species, even although GREEN had previously recognised the species as new but had not published it. If GREEN should feel aggrieved, he has himself to thank for omitting to publish the name with the description. The good-nature of botanists, however, often leads them to violate the strict rule, and, on the do as you would be done by principle, WHITE, if he find a manuscript name of GREEN'S, is very likely not only to adopt GREEN'S name if suitable, but to write after it "GREEN MS." It is possible to carry this good-nature too far. Our imaginary GREEN might, without study or examination, choose to give names to half the species in the herbarium, and a certain proportion of them might be found valid by WHITE in the course of his study of them, but as GREEN gives no evidence beyond affixing a mere name, that he has made any study of the genus or of the species such as would justify him in the eyes of other botanists in publishing a new species, it would be hard upon WHITE, who has made a careful study, and publishes his results, to compel him to adopt GREEN'S names. In all such rules some latitude and discretion must be allowed; thus, when we find, as we constantly do, in the herbarium a note of BENTHAM'S, the HOOKERS, or REICHENBACH, or FLANCHON, or GRAY, or other recognised botanist, it becomes almost imperative—if nothing prevent—to adopt the name, and to give the writer the credit for it, even though it be a mere manuscript name. One great objection to this practice is, of course, the absence of all guarantee that the manuscript name really represents the matured opinion of the writer, even of one as distinguished as those named. It may be a mere memorandum, subject to reconsideration. If, so then, it is a pity that it should be allowed to remain permanently on record. We should hardly have alluded to so technical a point here, were it not that the rule concerns horticulturists. After saying—we are alluding to DE CANDOLLE'S *Laws of Nomenclature*, adopted by the Paris Botanical Congress—that the botanist who first publishes an account of the species is the one who should attach his name to it as responsible for it, even though some one else had previously affixed a manuscript, that is, an unpublished, name to it, the rule goes on—the names made use of in gardens are distinguished—*provisis*—by the mention of the name of the author who first publishes them (not necessarily of him who really gave the name). By this we take it that a garden tally cannot be taken as authoritative—and very few would so regard it! Nevertheless, when men with such extensive knowledge of plants as Messrs. VEITCH, BULL, WILLIAMS, HENDERSON, LINDEN, or other of our nurserymen who introduce new plants choose to give a name to the plants made known by their enterprise, it is surely something more than a matter of courtesy to cite their names, always provided there is no valid reason to the contrary, yet according to strict rule such names have little more right to consideration than the manuscript memoranda on a herbarium sheet. The solution to the question depends a good deal on the view taken as to "publication." A manuscript note in the herbarium clearly is no publication, even though as a matter of deference it is sometimes treated as if it were so, but a name given by a nurseryman to an exhibited plant is a publication, inasmuch as it is open to any one to inspect the plant so offered to the public. The nurseryman's name, so published, if not vitiated from any cause, has decidedly higher claims than a manuscript name in the herbarium. The one remains in the herbarium and does not find its way into books, the other may be dispersed broadcast with the specimens to which it refers, in exactly the same way as the names with the "exsiccate," or collections of type specimens of the botanist, and to which the right of adoption is unhesitatingly accorded. Moreover, the names in question are inserted in catalogues often illustrated and accompanied by a description, which, if not comparative and strictly scientific, is still useful for botanical purposes, and these cata-

logues enjoy a much wider circulation than any strictly botanical publication. The outcome of all which is that art. 50 of the *Lois*, notwithstanding it appears to us that, as a matter of justice, garden names of the kind indicated and to which no objection can be raised on botanical grounds, should be adopted without hesitation by publishing botanists, and that they should not, unless there is good reason to the contrary, affix their own names to such a species without at least adding "hort. Linden," or "hort. Makoy," or whatever it may be. It must not be overlooked—though we fear the matter, if not overlooked, is greatly misunderstood even by botanists themselves—that the mere attaching an author's name at the end of the specific appellation of a plant, confers no honour on him who does so. The object of affixing the name is merely to fix the responsibility on him who gives the name. It does not in itself confer any distinction whatever on the author of the name, but simply indicates to those concerned who it is that has proposed it. Other botanists, and those who have the means of testing and judging, will form their own opinions as to the value of the name and the weight to be given to the utterances of its propounder, but as far as the mere name goes the familiar initials, "D. C.," have no more and no less weight than those of the veriest tyro. The question may seem one of purely technical interest, but no one who sees the preposterous names given to plants exhibited before the Floral Committee will deny its importance, or acquit the Royal Horticultural Society of neglect of duty, if it do not do something to check the piling on, helter-skelter, of Latin epithets for garden productions.

THE HULL BOTANIC GARDEN.—Mr. PHILIP MACMAHON, a young gardener employed at Kew, has, on the recommendation of the Curator, Mr. SMITH, been appointed to succeed the late Mr. NIVEN, as curator of the Hull Botanic Garden.

THE WEATHER.—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending February 27, issued by the Meteorological Office, London.—The weather during the earlier part of the period was moderately fine and dry, but towards the latter part it became very unsettled, with frequent, and in some places heavy, rain. The temperature has continued above the mean in all districts, the excess ranging from 4° in the west and east of England to 7° in the east of Scotland. The maxima were high for the season, a reading of 61° being recorded at Arlington, North Devon, on the 22d, while at many other stations the thermometer reached 55° or 59°. The minima ranged from 31° at Cambridge, Marlborough, and Cullompton, to 37° or 38° in Ireland. The rainfall has been a little less than the mean in "England E.," but rather more in nearly all other parts of the kingdom. Bright sunshine shows a decided decrease, and over the greater part of the country was very deficient. The percentages ranged from 4 in "England E." to 43 in "Scotland E." Depressions observed:—During the first few days pressure was highest in the south-west, and lowest over Scandinavia, where some deep depressions were shown. The wind was consequently generally moderate or light from north-west or west. On the 24th, however, the barometer fell quickly in the west, and by the 26th a large "trough" of very low pressure, within which were three distinct minima, stretched from the north of Ireland to the north of Scandinavia. This "trough" moved slowly in a south-easterly direction, at the same time filling up somewhat. These distributions of pressure caused the wind to shift to south or south-west (and subsequently to east in Scotland), and to increase to a fresh or strong gale on nearly all our coasts.

GARDENING APPOINTMENTS.—Mr. WILLIAM DAVIS, of Trentham Gardens, has succeeded Mr. FRISBY as Gardener and Forester to HENRY CHARLTON, Esq., M.P., Blankney, Lincolnshire. Mr. FRISBY has been Gardener at Blankney for the long term of thirty-one years, and has, we are pleased to know, retired on a handsome pension.—Mr. DAVID MCINTOSH, late Foreman at Bloxholm Hall, has been engaged as Gardener to Captain N. REEVE, Ashley-de-la-Laund, Sleaford.—Mr. JOSEPH HALL, Foreman to Mr. WILLARD, Holly Lodge, Highgate, has been engaged as Gardener to Lord BATEMAN, Shalton Court, Leominster.—Mr. GEORGE POTTS, late Foreman at Hookfield Grove, Epsom, has been engaged as Gardener to D. W. BRYANT, Esq., Surliton Hill, Surrey.

BOTANICAL COLLECTORS.

GEORGE BARCLAY.—In 1833 George Barclay, a well educated young gardener, native of Huntley, in Aberdeenshire, entered the service of the Royal Gardens, Kew. In 1835, through the instrumentality of Mr. Robert Brown, the Admiralty appointed a botanical collector to the ship *Sulphur*, under the command of Captain Beechey (afterwards Belcher), which was about to survey several parts of the west coast of America, and Barclay was selected for that duty. As in all cases of this kind, he was furnished with collecting boxes, paper for drying specimens, &c. The ship left Portsmouth on December 22, 1835; on the voyage they touched at Madeira, Teneriffe, and Rio de Janeiro, where they remained two days, which allowed Barclay to visit the botanic garden. The next place they touched at was St. Catherine's, where they remained several days, and he made large collections of herbarium specimens and seeds. They had a very rough passage round Cape Horn, which occupied five weeks, arriving at Valparaiso June 9, 1836, where the ship remained some time, allowing him to make several excursions into the valleys of the Andes. On leaving Valparaiso they proceeded northward touching at several ports, and arriving at Callao, Barclay had sufficient time to visit Lima and make an excursion to the Andes. On leaving Callao they proceeded northward, and arrived at Guayaquil in September, in the bay of which are the islands of Puna and Sumaca, which Barclay visited, describing them as densely covered with vegetation, abounding in climbing plants; he made a large collection of specimens and seeds.

In March, 1837, the ship arrived at Panama, and he had the opportunity of botanising in the Isthmus of Darien. They left Panama March 15, and surveyed the coast about San Blas, from thence proceeding to the Sandwich Islands, remaining at Oahoo a few days, during which time Barclay was busy collecting. On leaving the Sandwich Islands they again proceeded to the American coast, which they surveyed northward, arriving at Sitka, where they stopped a fortnight. They next visited Nootka Sound, where they remained two days, sailing from there to San Francisco in Upper California, where they remained until November 26. Here Barclay was allowed time to visit Sierra Nevada, and obtained cones of *Pinus Coulteri*, from seed of which was raised the fine specimen of that Pine now growing at Kew. The next place of stoppage was Monterey, where they remained two days, and at San Blas they stayed two weeks, which allowed time to botanise in the interior, and to ascend the volcano of Central America, 6000 feet high. The ship again arrived at Callao, and he says:—"During our stay I made excursions into the interior, and have done pretty well in the way of collecting, but unfortunately I was attacked by a band of robbers, who robbed me of all the money I had on me and other articles; in the affray I received a musket ball in the thigh, the bone was not injured and the wound does not offer to be troublesome." They left Callao the latter end of August, 1838, to survey the coast of Sierra Argul, and again arrived at Guayaquil, remaining there about a month. From thence they proceeded to Panama, and in October proceeded to survey the coast of Central America and New Granada. On leaving Panama the ship proceeded a second time to the Sandwich Islands from thence northward to Columbia River, where they arrived in October, 1839. In a letter he says:—"I have just returned from a most splendid trip on the plains of the Columbia. I have seen many of the plants which Douglas sent home, but there are more yet to be sent. . . . I am sorry to say that the botanical collectors, Wallace and Banks, were drowned in this river a few months ago. I have seen the guide who was in the boat with them, and made particular inquiries, as it is said that the upsetting of the boat was caused by its being surrounded by Indians. This was not the case; the upset was accidental." On leaving Columbia they proceeded south, surveying parts of the coast, which they ultimately left for home, touching at the Sandwich Islands, Otaheite, Fiji, and the north coast of New Guinea, arriving at Singapore in October, 1840, where, consequent on the war with China, instructions were found for the ship to join the China fleet. Accordingly, Mr. Barclay with his collection took passage in an English bark bound direct for London, where he arrived in February, 1841, having been on board ship a little over five years. This surveying expedition, like

summer the Tamarisk, that grows so freely anywhere in sandy soil near the sea coast, is always available. A large bush or two of this is a great ornament in any garden, and is quite worth cultivating in pots. Coloured leaves, such as those of some of the Crotons, like *C. majestica* and others, that are long and narrow, are not made half the use of they might be, as what can be more beautiful than they for mixing in with cut bloom, especially with such as is white? For lasting, I know of nothing equal to them, and they are grand when seen under artificial light. 7. 5.

Myosotis dissitiflora.—The illustrations we now give of the nuts (commonly called seeds) of *Myosotis dissitiflora* (fig. 44) will be interesting both to seed-men

FIG. 44.—SEVERAL "SEEDS" OF MYOSOTIS DISSITIFLORA AND SEVERAL SEEDS OF M. SILVATICA.

and to botanists. To seedmen, because they furnish a means of identification which will be useful in enabling them to distinguish them from the so-called seeds of *M. silvatica* and alpestris; to botanists, because they add another testimony to the distinctness of the species. It will be remembered that the species was introduced from Switzerland by Mr. Atkins, of Paiswick, and was described by Mr. Baker as a new species in our columns, 1868, p. 599. That some doubt should have arisen as to the existence of a new species from a country so well worked as Switzerland was natural enough, but the character now depicted, in addition to those cited by Mr. Baker, renders the case complete. The so-called seeds of *Myosotis* are really seed-vessels, fruits, or nuts containing the seeds in their interior. In most cases these nuts spring from the receptacle of the flower without the intervention of any stalk, as in *M. dissitiflora*, figured for purposes of comparison; but in *M. silvatica*, each nut is borne upon a small white stalk, as shown in the sketch. It is curious that of all the European species described and figured by Reichenbach the only other species that possesses this little stalk is *M. sparsiflora*, the name of which indicates a resemblance in the inflorescence to *M. dissitiflora*, but which in other respects is widely different. *Anchusa sempervirens* has its nuts supported by a similar stalk. The small white process at the rounded end of the nut then serves to distinguish the so-called seeds of *M. dissitiflora* from those of any species likely to be confounded with it. We owe this useful little means of knowing what is what to Mr. Barr, who brought it under our notice. Ed.

Abnormal Growth of a Fungus.—Two curious specimens of abnormal growth in fungi were found last week at Hardingham, in Norfolk. The honey-

FIG. 45.—MORRILL-LIKE AGARIC.

combed pileus, 4-inch in diameter, looked something like a liliputian Morell, with a stem 2 inches long and 2 lines thick, but a section through it showed that the resemblance was merely external. I sent one specimen to Mr. Worthington Smith, who referred me to a short note by himself which appeared in the *Gardener's Chronicle* for March 9, 1878, p. 299, in

which a precisely similar growth is figured and described. These latter Mr. Smith considered to be specimens of *Agaricus furfuraceus*, many normal specimens occurring among the others. I have no doubt that the Norfolk plants are deformed specimens of the same or some very closely allied *Agaric*. 7. 31. D. P.

Casuarina sumatrana.—A fine specimen of this lovely plant is producing a quantity of cones in the gardens at Wilderness Park, Sevenoaks, Mr. Carlton, the gardener, grows this extensively for table work; it is a gem for that purpose, and when large, as seen here, is a lovely object. O.

Petunias.—I had a bed, 10 feet by 7, filled with single *Petunia*, planted about 1 foot apart, or perhaps rather less. The soil had been well dug over after the bull crops of Tulips, Hyacinths, and Crocuses, which made a good show, had done flowering), and a large barrowful of old manure dug in with it. Three dozen plants, costing about 5s., grown in small pots, were turned out into the newly-made bed early in April last, and for several months there was continuous bloom of large variegated self-coloured flowers that made a good show, in the wet and cold weather in September made them shabby. Carefully tended and pegged down occasionally, the bloom was gay and incessant. Larger or smaller patches of this bright flower would be very suitable generally for suburban gardening. Nothing is easier than their culture; in fact, they require only the most ordinary attention. Where no gardener is kept, or only a man occasionally called in to "flily up" a small plot, it is sufficient if occasional visits are paid to the bed to see that the pegging-down is neatly carried out (and large hair-pins would make good pegs), dead flowers and weeds taken away, and water given during drought—not much for the lady of the house to look after—*not per alium ut per se*—to secure a brilliant bed during all the summer months. The young plants can be purchased for less than 2s. per dozen, if separated from a clump and dibbled in; but young potted plants are altogether more satisfactory, and make at once strong growth. Those I had planted in the bed, &c., came, to my regret, only 7-, and certainly the brilliancy and continuance of the flowers was a good result from so small an outlay. Any shape of bed may of course be adopted, according to the adaptability of the ground, and suburban gardeners may thank you for the hint, if you think it proper to give it to them, for the coming summer. Several of the plants had exceptionally large flowers, in which the anther leadlets were quite striking. The florist from whom I bought them said the seed was ordinary from which they were raised, and that he never noticed a similar growth; neither had I ever seen anything of the kind either here or in Bangalore where I used to grow them freely in effective masses for their gay appearance and delicate scent. But it may be common enough. The question that occurred to me was this:—Would the seed saved from the best specimens of this sporting kind, likely to produce double flowers, or exceptionally fine or "pedigree" flowers? In my neighbour's garden I found a double *Petunia* sending out anther leaves the same way. 7. *Puck*, 13, *Elton's Case, Blackheath, S.E.* [In the specimens sent the "connective" of the anther was prolonged into a small petal—a condition not uncommon in *Petunias*. Ed.]

Spring Flowers.—I do not remember to have seen so many spring flowers in bloom at so early a period of the year. Fortunately large trees have shown less disposition to bud forth. The large beds of *Saxifraga lingulata*, *Anemone fulgens*, *A. blanda*, are really wonderful in their perfection of bloom and precocity. The spring garden will be very bright and gay early in March, when *Aubrietia*, *Arabis*, *Heath*, and *Primrose* will be in full beauty. *Rhododendron daluricum*, *R. praecox superbum*, and *R. Nobileanum* are making a great show at this moment. *Empetrum verna* is blooming more abundantly now than I ever saw it. W. Ingram, *Edwin*.

Market Gardeners' Liabilities.—When so much is being written and said about the responsibilities of landlords and in favour of tenants of land it is worth while to consider a case that is not an apocryphal one but a reality. Some years since a market gardener took a lease for twenty-one years at the high rental of £10 per acre annually—30 acres of land in a West Middlesex parish, that had been set apart under an Enclosure Act as poor's land, and which was in trust with the parish authorities, the rental being devoted to the purchase of coal chiefly, for distribution annually amongst the poorer residents as compensation for the loss of rights of turbery, &c., once enjoyed by all the inhabitants prior to the enclosure. The land at the time of letting was in good condition and fully cropped throughout with top and bush fruit. After a few years, the tenant finding the rent was too heavy

HOME CORRESPONDENCE.

The Fernery at Nash Court, Faversham.—This lovely fernery was erected for Mrs. Lade about two seasons ago, and is a span-roofed house about 30 feet long, 22 feet wide, and 15 feet high. A path is not made twice a year, but the luxuriant growth the Free Ferns are making will soon render them too large for their positions—some of the Dicksonias, *Cyathea*, *Alsophilas*, &c., already measure 17 feet across. The interior arrangement is very good, consisting of a winding walk, which at almost every step brings a fresh object into view. The waterfall arrangements are also very effective. I was pleased to see the distinct *Adiantum Williamsii*, which has been over 4 feet through the fern for such work, also *Microlepia laria cristata*, *Adiantum concinnum* *Var. A. decorum*, *A. cardiolobum*, and the lovely *A. gracillimum*, *Todeas*, *Woodwardia*, *Lomaria*, and *Lycopodium* of all the best and most suitable sorts are here to be seen growing luxuriantly. Pockets are left for inserting in the summer season various neo-foliaged plants, such as coloured *Dracenas*, *Caladiums*, &c., which form a lively and beautiful contrast. The whole of this work was carried out by Mr. Humphrey, the gardener, and his great credit upon his abilities, for he has evidently studied well the natural requirements of the various plants used in this lovely place. O.

Green with Cut Flowers.—There can be no question, I think, but that all flowers look best with their own foliage, but unfortunately we cannot at all times get enough of it, and have to resort to Ferns and other plants to make good the deficiency. At this season, and as long as it can be had forced, I find nothing equal to Solomon's Seal, the lovely delicate tint of the leaves of which are quite unvariegated. Dug up from the open and put thickly in pots or boxes of light soil in heat it soon grows, and yields a long succession of gracefully arching shoots for cutting, which, thickly hung with their silvery bell-shaped blossoms, are a great ornament and finish to any vase or glass they may be placed in. The plan we adopt is to make a plantation under the Apple trees or among the Gooseberry bushes, so as to have plenty to run to, and the roots are stood away in the pots when done with for forcing and planted again. The first year they are not so strong, but that is often an advantage, as the smaller sprays are sometimes more useful for working up in bouquets. The leaves of *Spirea japonica* are also very good, but to last they must be fully grown and nearly mature. For drooping over the sides of tall glasses nothing can be better than the small, deeply cut Ivies, either plain or variegated, as they all have a natural look. Sweet Brier is most valuable, and as its scent is so delicious and refreshing, no vase should be without a sprig or two, which will perfume the air of a large room with rich odour. In the depth of winter we often use sprays of the large glossy leaved Box, and sometimes *Berberis Aquifolia*, the foliage of which, when set thin on the branches, is as nice-looking as anything that can be had. *Cupressus Lawsoniana*, with its thin, gracefully fern-like pendulous shoots, is very effective; and in spring and

a lurch, induced the trustees, with the consent of the Charity Commissioners, to lower it to £8 per acre. Some four or five years of the lease have yet to run, but now the tenant shows such disregard of the future letting value of the orchard, that not only has the soil become throughout quite choked with couch and other perennial grasses, but for two years not one of the fruit bushes has been pruned, so that the crop is fast deteriorating. The point upon which information is desired is as to the duty of the tenant towards the land and the power of the trustees or parishioners as the landlord to enforce penalties against the tenant for thus permitting such obvious depreciation of the property to take place. It is evident that, should this neglect be continued, the land when the lease expires will be worth not more than one-third what is now paid for it, and the interests of the poor of the parish must greatly suffer. *A. P.*

Cinerarias from Seed.—I quite agree with Mr. Culverwell's remarks respecting Cinerarias raised from seeds at p. 229. We have now a fine lot in bloom from seeds, and have had for some weeks past, the flowers being everything in colour, size, substance, and form, one could wish for, and grown with half the trouble required for named sorts. *A. M.*

Salvia cerulea alba.—At the beginning, one may almost say, of the plant growing season a word of seasonable advice may be useful to plant growers. Those who live within a few miles of the metropolis, and who have frequent opportunities of visiting the leading shows and nurseries, seldom think of their brethren who are distant from London some hundreds of miles, and whose opportunities for obtaining knowledge about new or useful plants is solely derived from the horticultural press. Gardeners having large conservatories to keep gay—many of them are difficult enough even to fill—should grow *Salvia* more extensively than they do, and in greater variety. Writing as a gardener, and not as a critic, I have no hesitations in recommending the extensive cultivation of this class of plants. They are not dear to purchase, are easily grown, and as flowering plants they possess a grace and beauty exclusively their own. I have mentioned the variety above named having seen it in flower only a few days ago, its blue and white flowers being quite fresh and light, and that at the end of February. When we know—and there is no harm in writing the naked truth—the hundreds of private gardens where only two or three of the old varieties have been grown for the last quarter of a century, and when we remember that a good collection may be bought for a few shillings, I think it follows that an addition to the general stock of conservatory plants would not be unacceptable where much variety has not previously existed. So much is expected from gardeners now-a-days, and in so short a time, that the nearest way to accomplish success will be by cultivating extensively plants of rapid growth that are readily obtained and attractive in appearance. *W. Hand.*

FRUIT NOTES.

Apple, Mela Carlo.—Three or four months ago enquiry was made by one of your correspondents about the Mela Carlo Apple. I did not see any answer, so I send specimens. They were grown in the open, trained against the stone pillar of a Dutch barn facing the south. Their condition would have been better had I not taken them at the end of October a journey of 160 miles. They have remained ever since in paper in the basket in which they were carried. I had only four, and those were the first (the tree about twelve years old) had borne. The colour is not as high as I expected. *Philomelos.* [The fruits received are of medium size, ovate in form, with a small, depressed, closed eye, and short, slender fruit-stalk set in a deep basin, the skin of a clear yellow colour all over. The flavour is said to be most delicious, but these were past their best. *Ed.*]

King of the Pippins and Golden Winter Pearmain.—I do not see that your correspondent, John Scott, has thrown much light on the difference of opinion that prevails in regard to these two kinds of Apples, for in his *Ochardist*, p. 88, that he quotes from, he says that Golden Winter Pearmain far surpasses King of the Pippins in richness and flavour, yet, in his note on the subject, p. 82 of the last volume of the *Gardeners' Chronicle*, he makes it appear that King of the Pippins is best. How does he make the two statements agree? My own experience of the two fruits is that the flesh of King of the Pippins is yellowish, firm, with a nice flavour, and keeps much longer than Golden Winter Pearmain, whose flesh is white, with no flavour—only fit to grow

for its handsome appearance. I think Mr. Culverwell and Mr. Saul must have got Golden Winter Pearmain for King of the Pippins. *A. T. S.*

The "Irish Crofter" Apple.—I imagine the Irish Crofter mentioned in p. 226 as being selected by Dr. Lucas as one of the best ten Canadians, must be either the Early Crofton (Irish Peach), or the Scarlet Crofton, another Irish Apple. The first is one of the best early Apples we have, becoming ripe about the first week in August, the latter in December. *Lewis A. Killick, Mount Pleasant, Maidstone.*

THE GOOSEBERRY.

It is somewhat remarkable that the most wholesome, and by no means the least delicious of the fruits cultivated in this country, should be, what few of them are, indigenous. But such is in reality the case as regards the Gooseberry, which is found wild in various localities in this country, and is known to botanists under the names of *Ribes grossularia* and *Ribes uva-crispa*, or the rough and the smooth Gooseberry. They belong to the natural order, Grossulariaceæ, an order which contains only one genus, that of the Ribes, which is, however, composed of many species, several of which are indigenous to Britain, others to the south of Europe, a few to Siberia, and some to North America. None of them, however, attain to the dignity of trees, but are all comparatively dwarf-growing shrubs, some of them remarkable for the beauty of their flowers; others, in addition to the two species mentioned, bearing useful fruit, such as the red, the white, and black Currants. The modern varieties of the Gooseberry are no doubt derived from a blending of the two species named; if, indeed, they ought to be regarded as distinct species, or if they are so considered they are certainly not separated by any very hard or fast line, as there are now many varieties which can hardly be said to be rough, and yet are not altogether smooth. But they have naturally, as it were, divided themselves into four distinct sections, viz., sorts bearing green, red, yellow, and white coloured fruit, and well-defined varieties in each section are very numerous.

The comparatively cool, moist atmosphere of the northern counties of England and of Scotland is better suited to the development of this fruit than the light land and drier air of some of the southern and south-eastern parts of England. And Lancashire has long been celebrated for its large and brooding napsian examples of this fruit; and plants of the Lancashire show varieties, as they are called, generally command a higher price, forming as they do a distinct class of this fruit. But it does not follow that the large-fruited kinds are also of the best quality; indeed, the reverse of this is rather in reality the case. But in each of the four sections there are numerous varieties remarkable for their quality or fine flavour, as well as for their immense size.

Like most of other fruits, the Gooseberry succeeds best in soil of moderately good quality, although it cannot be said to be very particular in this respect, but will generally succeed in any ordinary good garden soil. The plants are generally grown in the form of bushes, and should be planted in rows or lines at a distance from each other of not less than 7 feet. They should be annually pruned, and the branches should not be allowed to become too crowded, or the fruit will not be so fine as would otherwise be the case; and it is generally advisable to defer the annual pruning until the spring is somewhat advanced and the buds ready to unfold, as the bushes are liable to be attacked by bullfinches and other predators, who will sometimes, before being observed, strip off the swelling buds from the branches, and thus frustrate all expectations of a crop of fruit; and this attack, if made upon bushes which have been pruned, is more serious than when made upon them before this operation is performed, when there are, of course, more buds to spare. Late spring frosts also not infrequently prove destructive to this crop, so that in most cases it is advisable to defer pruning until all danger from this cause has passed.

The Gooseberry is also liable to be attacked by fungoid diseases, which sometimes prove troublesome, but possibly its most formidable enemy by far is the caterpillar, and for this pest the bushes should be carefully watched during the early spring months; and

there is possibly no better remedy for this evil than the application of powdered hellebore, which may either be applied to the bushes in the form of a powder, or in the form of a decoction of the same, which should be of about the strength of 1 lb. of the powder to 10 gallons of rain-water, and this should be allowed to stand some forty-eight hours before being used, and should be applied to the bushes with a syringe during a still evening; one dressing will generally prove a cure, but if not it should be repeated. Two years ago, for want of attention to this matter, in many gardens all over the country plantations of Gooseberries were to be seen with the bushes divested of every leaf for want of applying in due time this or some other simple remedy, and the consequence was that any fruit such plants bore was, of course, flavourless, if not altogether worthless.

Although, as has been said, this useful and delicious fruit is generally grown in the form of comparatively low or squat bushes, it is nevertheless amenable to other methods of training, such as the standard form, and trained to a north or other wall, where such late sorts as the Red Warrington may be kept in good condition until the middle or end of November, and we have some recollection of seeing in a garden in Perthshire years ago a single plant of the variety named covering the entire east end of a large building upwards of 30 feet high, and clothing many square yards of wall, and the plant was said to annually furnish heavy crops of fruit of excellent quality. We have never, however, seen this fruit more successfully grown than in the form of pyramids, and this was accomplished in the following manner:—The portion of land intended for the plantation was heavily manured and trenched; the surface was made quite level, and lines were drawn upon it each way at a distance of 6½ or 7 feet from each other, that is, the lines were drawn from north to south and from east to west, and at each intersection of these lines a strong Larch post was fixed in the soil; the posts were some 6 or 8 inches in diameter at the lower end, which had previously been well charred. The posts were then cut to a uniform height of 7 feet above the level of the soil, and in order to give increased stability to them a strong cord or wire was made to extend from the top of one post to that of the next, and so on. A healthy young Gooseberry tree was planted upon the south side of each post, and from each plant four shoots were allowed to grow, which were either nailed or tied to the posts, while from these leading shoots lateral branches were allowed to extend themselves, so as to get the plants into the desired pyramidal form; and as soon as the leading shoots reached the top of the post a shoot was trained along each wire or cord. When the plants forming the plantation attained to their full development the thing was considered unique and was much admired, and during the fruit season was much resorted to by ladies and others, as the fruit could be readily picked from the branches without the trouble of stooping to do so.

The Gooseberry has, we believe, been successfully grown under glass in orchard-houses and similar structures, but it is doubtful if it would submit to anything like forcing, even if this were necessary or desirable, which can hardly be said to be the case. It has already been said that the Gooseberry is the most wholesome of fruit, and when quite ripe most of its varieties are delicious, and in all stages of its development it is useful; when in a green and unripe condition it is much used and appreciated for culinary purposes, and when ripe some of the varieties are made into the most delicious preserves, and green Gooseberry wine is even said to have done duty for champagne. *J. Griev.*

THE SO-CALLED COMPASS PLANTS.

THE American Compass-plant was figured in the *Botanical Magazine* last year, plate 6534, and we reprinted the account there given of it by Dr. Asa Gray, and this brought several interesting communications (*Gard. Chron.*, n.s., xv., pp. 74, 276, 571, and 699) respecting this plant. And in one of these communications—that from Dr. Engelmann (*l.c.*, p. 276)—it is stated that other Composite with vertical leaf-blades have the stomates equally distributed on both surfaces of the leaf. This is especially the case, the writer states, with *Lactuca scariola*, a plant unknown here (St. Louis) formerly, but extremely abundant of late years in waste places. The leaves not only assume a vertical position, but also a meridional one, similar to those of the Silphium, though perhaps less pro-

nounced. The fact that the leaves of *Lactuca scariola* assume vertical positions has long been known, and is mentioned in several books; but it has only lately been recorded that they also stand in a meridional plane—that is, point north and south.

Whether Dr. Engelmann was the first to record this fact, as quoted above, or Professor E. Stahl, of Jena, we cannot say. But the latter botanist last year published an account of some experiments and observations he had made on this plant. Dr. Stahl's experiments were undertaken for the purpose of determining the cause of this remarkable orientation of the leaves. In order to determine the manner in which light affects the leaves of this *Lactuca*, Dr. Stahl cultivated a number of plants in diffused daylight. Plants cultivated in a room and only exposed to the light that entered at a north window lent the tips of their stems towards the window, whereas the leaves turned themselves vertically to the incidence of the light. Plants growing in ditches or among bushes, so that they were only exposed during growth to the diffused light of the firmament, had perfectly horizontal leaves. From this experiment it seems that the leaves of *Lactuca scariola* behave exactly like those of other dicotyledons under the influence of feeble light—that is to say, they are what Darwin terms diateliotropic, or in a position transverse to the light by which it is caused.

In order to ascertain the effects of sunlight on the position of the leaves the following experiment was carried out:—Two flower-pots with plants of equal age were taken; the one was exposed from 10 A.M. to 3 P.M. to direct sunlight, and kept in the dark the rest of the time; and the other was kept in the dark from 10 to 3 and exposed the rest of the time. As the weather was continuously fine during the experiment the plants enjoyed direct sunlight during the hours of exposure. The plants grew, though slowly. The newly formed leaves of the plants exposed during the mid-day hours showed no difference to the meridional position, whereas it was distinctly noticeable in the plants exposed up to 10 and after 3 o'clock.

As the foregoing experiment was not altogether satisfactory it was repeated in the following modified manner:—Some plants growing in the open air were so covered by a board resting on four posts that they were sheltered from direct sunlight during the mid-day hours, but exposed to it during the earlier morning and later afternoon hours. In these plants the newly formed leaves assumed the meridional position as decidedly as those of plants exposed all day to direct sunlight. Other plants were placed among bushes, so that the sun could only fall upon them when at a great altitude. Although these plants received diffused light all day long from above, the leaves were by no means horizontal. The effect of the sun-light was exemplified in the south or south-west direction of the upper surface of the leaf.

That the meridional position of the leaves of plants standing quite free is caused by the light of the sun on the horizon is evident. Dr. Stahl says, from the following experiment:—

A pot of young plants was placed near a window looking north, in which position the plants were exposed to direct sunlight for a few hours after sunrise and before sunset. All the leaves developed under these conditions inclined their tips towards the north, and the upper surface was turned either to the east or to the west. When the plants were removed so far from the window that the sun did not shine upon them at all, the above described vertical position to the diffused light.

This phenomenon is not an uncommon one, but the leaves of *Lactuca scariola* are much more sensitive to intense light than those of many other plants. The leaves of many Papilionaceæ—beans, for example—assume such a position during intense heat that the least surface is exposed to the sun, thereby avoiding excessive heat and light. *H. B. H.*

The Poultry Yard.

WINTER LAYERS.—The particular white hens to which I referred last week as being such capital winter layers, I now learn, are either the product of a cross between white Dorkings and white Leghorns, or between the former and white Spanish breeds. I incline to the former cross, especially as the Leghorns are such capital winter layers, but they have yellow legs and flesh, not a desirable table feature. My fowls are white throughout. *D. B.*

Obituary.

ENGLISH visitors to Ghent who have experienced the courtesy of Count KERCHOVE DE DENTERGHEM, late Burgomaster of Ghent, will receive the announcement of his death, which occurred on the 21st ult., with sincere regret. The Count—a member of one of the oldest families in Flanders—took a leading part in agricultural and horticultural matters, and in this capacity he came into contact with English horticulturists, and always in such a manner as to secure their respect. The Winter Garden erected at Ghent by the late Count is one of the sights of that interesting city, and was freely opened for the inspection of visitors. We took occasion in 1875, vol. iii., to publish some illustrations of this noble house, in which a tropical ravine, with Palms in great beauty and variety, Tree Ferns, rocks, waterfalls, &c., is successfully and artistically imitated; and in 1876, vol. v., p. 181, we published a portrait of the deceased nobleman. Count de Kerchove identified himself with everything that was likely to promote the prosperity, not only of his native city, but of Flanders—indeed, of his country generally. It is no matter for surprise, therefore, to find that he was honoured alike by the Government and by his fellow-citizens.

Count de Kerchove was born in Ghent in 1819, and in early life took high honours at the Ghent School of Engineering. In 1848 he became a member of the Royal Society of Agriculture and Botany of Ghent; and in 1859 became honorary President of the society, and presided in this capacity over the great Exhibitions of 1868, 1873, and 1878. On the death of M. Edmond de Ghellinc de Walle, in April, 1875, Count Kerchove was nominated President of the Society, and also of the Cercle d'Arboriculture. In 1851 the Count was selected as "Conseiller Provincial" for the canton of Ghent, an office which he filled until 1864, when he was elected a member of the Chamber of Representatives for Ghent—a position to which he was several times re-elected. In 1857 his fellow-citizens elected him as "Conseiller Communal," and the late King Leopold appointed him burgomaster of the city—a high office, which he filled with honour and distinction, his government being marked by energy, firmness under circumstances of great difficulty, and great courtesy. Horticulturists will specially feel his loss, for the reasons already assigned. The late gentleman's eldest son, Count Oswald de Kerchove, Governor of the province of Hainault, who now succeeds to his father's title, has associated himself even more intimately with horticulture, and with the members of the horticultural press; on which account we feel that we do but interpret the feelings of English lovers of gardening, connected by so many ties with the old Flemish city, when we offer to the family a cordial expression of respectful sympathy with them in their distress.

MR. E. FANCOURT.—In our obituary column last week appeared a brief notice of the demise of Mr. Edwin Fancourt, a name doubtless familiar to numbers not personally acquainted with him, as it was to the very many in one way or other connected with gardening who were. For it would be difficult to imagine any individual connected with the nursery business of this kingdom who has not at least heard of the most renowned of propagators, father and son, which this country has ever known. The remark is often made that it rarely happens that when a man has excelled in any particular art or calling, that his mantle descends upon his son. Yet here, at all events, was an exception; for, although the elder Fancourt has been looked on as the father of English plant propagators, his son, following his footsteps, was equally successful. A word here may not be out of place respecting Mr. John Fancourt, the father of the deceased. He commenced his career in connection with the trade in 1814, at the Bedford Nursery, New Road (Mr. Smith's); thence he went to the Ball's Pond Nursery; afterwards to the Clapton Nursery; and finally to Messrs. Henderson, at Edgware Road, where he remained thirty-three years. Edwin was born on the site now occupied by the Euston Station, a circumstance which reminds us of the ceaseless extension of bricks and mortar on this as on other sides of London—an extension as irresistible as the wave of lava from a volcano in eruption. At Messrs. Henderson's his father taught him the mode of multiplying in quantity plants the most difficult to increase, and soon he became an expert in the art. From the

Pine-apple Nursery he took a turn in a private establishment—the Marquis of Downshire's, after which he returned to the trade, and amongst other places was foreman with Knight & Perry, King's Road, Chelsea; Cant, of Colchester; Standish, of Ascot; and again at the Pine-apple Nursery; afterwards with Mr. William Cutbush, of the Barnet Nursery, for whom he was manager eighteen years; from there he went to Messrs. Osborn, of Fulham, where he stayed until shortly previous to his engagement with Messrs. James Dickson & Sons, of Chester. Here he remained until his death, which occurred on February 2, at which time he was in his fifty-seventh year. Although only a comparatively short time with Messrs. Dickson, we believe he earned their full confidence and esteem. During his long and painful illness these gentlemen treated him with the greatest kindness—a kindness alike worthy of the employers and the employed. Those who knew Mr. Fancourt intimately need not be told of his genial nature and unassuming manner, which at once enabled him to make a host of friends, and keep them. He died of heart-disease, and was buried at South Mimms, near Barnet. He has left a widow, two daughters, and four sons.

- Feb. 23.—A fine day, though overcast and dull. Fine night; dark sky.
- 24.—A fine but overcast and dull day. Fine night; thin clouds.
- 25.—A dull, cloudy, rainy day. Rough night, thin drizzling rain.
- 26.—Strong wind all day, with rain. Windy night.
- 27.—A fine bright day; warm; rain. Dull night.
- 28.—A dull, damp morning. A fine afternoon; overcast. Rain all the evening.
- Mar. 1.—A fine day; sun shining; frequent showers. Rain-bow seen at 4 h. 53 m. Overcast; occasional rain, and strong wind at night.

LONDON: Atmospheric Pressure.—During the week ending February 25, the reading of the barometer at the level of the sea increased from 30.30 inches at the beginning of the week to 30.85 inches by 9 A.M. on the 20th, decreased to 30.62 inches by 9 A.M. on the 21st, increased to 30.72 inches by midnight of the same day, and was 29.51 inches at the end of the week.

The mean reading for the week at the level of the sea was 30.41 inches, being 0.29 inch higher than last week, and 0.42 inch above the average of the week.

Temperature.—The highest temperature in the shade during the week was 53° 5, on the 22d. On the 23d the highest temperature reached was 46°. The mean of the seven high day temperatures was 49° 4.

The lowest temperature in the shade in the week was 33° 5, on the 20th; on the 25th the lowest temperature was 43° 5. The mean of the seven lowest temperatures was 39° 7.

The greatest range of temperature in one day was 13°, on the 20th and 21st; the smallest was 5°, on the 23d. The mean of the seven daily ranges, 9° 7.

The mean temperatures were on the 19th, 42° 5; on the 20th, 40° 4; on the 21st, 40° 1; on the 22d, 40° 8; on the 23d, 42° 6; on the 24th, 44° 3; on the 25th, 49°. And these were all above their averages by 3° 7, 1° 5, 7°, 7° 7, 3° 4, 5° and 9° 5 respectively.

The temperature of the air for the week was

THE "AUTOMATON."

THE BEST GENERAL PURPOSE MACHINE.

The "AUTOMATON" Lawn Mowers are thoroughly strong, well-made, and durable machines, and the best suited for general work and Gardeners' use. They cut the grass perfectly, leave no ribs, but produce a smooth velvety surface on the lawn, and are light in draught.

The "AUTOMATONS" have front rollers for general work, and *scute* rollers for cutting long grass, or when it is necessary to roll the grass in front of the cutters. They have the best self-sharpening knives of steel and iron rolled together, and automatic silent drives.

THE HIGHEST AWARDED.

COMPLETE PRICE LISTS FREE BY POST.

STOCK KEPT IN LONDON at Arch 92, Spitalfields Station, Bethnal Green, E., and Machines may be ordered from any respectable Ironmonger.

Ransomes, Head & Jefferies, ORWELL WORKS, IPSWICH.

The "WORLD" (late "GLOBE") Lawn Mowers are intended for cutting long grass; and, whilst similar to the Lawn Mowers imported from America, have the special advantages of the more accurate fitting and general durability of English manufacture and perfect adjustment.

The "WORLDS" will cut wet, dry, long, or short grass without clogging, and cut off almost all the "beats." They leave the surface smoother than similar machines, and are well adapted for getting over a large amount of work with little labour.

SIZES, 8 to 22 inches.

MELBOURNE EXHIBITION, 1881.

Made of thoroughly well-seasoned Red Deal, 7 1/2 inches thick, ventilators at top and in front, painted two coats, and glass cut to size; door with lock and key, guttering and down pipe. Makers of the "65 GUINEA GREENHOUSE," size 10 feet by 6 feet. These houses are made in lights, have all erected in our own shops, and can readily be put together again. Many sizes in stock ready for despatch. Full particulars and illustrations and prices on application. See also advertisement alternate weeks. **MESSRS. JONES & CO** Loughborough, Leicestershire.

RIPPINGILLE'S PATENT PROPAGATING PLANT FRAME. Heated by Patent Stove, to Burn Petroleum and other Mineral Oils.

The Simplest and Best Invention ever introduced for RAISING SEEDS, STRIKING CUTTINGS, &c.

The only Frame of the kind for Outdoor Use. The above illustration represents Rippingille's Patent Outdoor Plant Frame, which is so constructed that it will not blow out during the roughest weather; it is made upon the most scientific principles, but is so simple that it is impossible to get out of order, and in economy it is unequalled, the cost of burning being only FROM A FARTHING TO A HALFPENNY PER DAY.

The Stove will burn from thirty-six to forty hours without attention. The products of combustion do not enter the Frame at all, but at the same time all the heat is completely utilised. It is disconnected from the Frame for trimming the wick, lighting, replenishing with oil, &c. The top of frame slides off either way, and is entirely removable; this is very convenient for Planting or removing Cuttings, Watering, Ventilating, &c. The heat attained is from 75° to 90° Fahrenheit, which is considered the best temperature for Focusing or Propagating purposes.

PRESS OPINIONS. The "Journal of Horticulture."—"A valuable aid to Amateur Gardeners." The "Gardener."—"It is a handy Plant Frame, likely to be much used when better known." The "Gardener's Magazine."—"Rippingille's Propagating Frame is the most valuable invention." The "Horticultural Record."—"This Frame ought to be in every small Garden, so that its owner could raise his or her flowers from seeds and cuttings, which gives so much greater zest to the pleasures attached to Amateur Gardening." Sent packed free and carriage paid to any Railway Station in England.

Illustrated LIST, with full particulars, further Press Opinions, Testimonials, sizes, &c., in application to **THE HOLBORN LAMP & STOVE CO., 118, HOLBORN, LONDON, W.C.**

LEAN-TO OR SPAN ORCHARD HOUSES, consisting of top and front sashes in red deal framing, channelled and glazed without putty with 21-oz. glass. Sashes removable when not required for the trees. Price, 12. 6d. per foot super—carriage paid. Specimens on view, Catalogues and Price Lists free. **W. PARHAM, Northgate Works, Bath, and 411, Oxford Street, London, W.**

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler with the following improvements—viz, the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought-iron are not liable to crack. They are made of the following sizes:—

Sizes.	To heat of 4-in. Pipe.	Price.		
High. 20 in.	Wide. 18 in.	Long. 18 "	Feet 3 3/4	£ 1 d.
20 "	18 "	24 "	4 0 0	8 0 0
20 "	18 "	30 "	5 0 0	9 0 0
24 "	24 "	24 "	7 0 0	12 0 0
24 "	24 "	30 "	8 5 0	14 0 0
24 "	24 "	36 "	10 0 0	16 0 0
24 "	24 "	42 "	12 0 0	20 0 0
28 "	28 "	60 "	15 0 0	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Ballham Hill, S.W., May 28, 1879. "Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS of HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E. When ordering Boilers please refer to the above advertisement.

HILL and SMITH'S BLACK VARNISH
 for Preserving Ironwork, Wood, or Stone.
 (Registered Trade Mark.)

This VARNISH is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was invented upwards of thirty years ago by the inventors, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many high nobles and the Nobility and Gentry, from whom the most flattering testimonials have been received.

Sold in Casks of about 30 gallons each, at 12s. 6d. per gallon at the Manufactory, or 12s. 6d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL.
 "Pierrefield Park, June 21, 1876.—SIR,—I have this day forwarded from Chepstow to your address a black varnish cask, to be filled and returned with six good Varnishes as the last we had, which I candidly admit was the best we ever had. Address Varnish to Pierrefield Park, Chepstow.—I am, Sir, yours respectfully, Wm. Cook."
CAUTION—HILL & SMITH would particularly warn their Customers against the various cheap Varnishes now so much advertised.

H. & S.'S Varnish has been an article of common use on most of the large estates in the kingdom for upwards of thirty years; and their constantly increasing trade in it, and the numerous Testimonials they receive, stamp it as a truly genuine article. Every cask is legibly marked with their name and Registered Trade mark as above, without which none is genuine.
 Large Illustrations of Catalogue of Fencing, Hurdles, Field and Entrance Gates, &c., sent free on application to

IMPROVER, in a Gentleman's Garden.—Age 19; five years' excellent character.—JOSEPH HORNER, Cross Lane, Leeds.

IMPROVER.—Age 19; seven years' character.—Apply, by letter, in person, to JOHN CLARKE, The Gardens, Beaumont Park, Leicestershire.

IMPROVER, in a Garden where several men are kept.—Age 18; good character.—R. PAWSEY, Admiral Luard's, The Lodge, Witham, Essex.

IMPROVER, in the Garden, by a thoroughly good working young man. A Premium if required, if the wages are good.—GARDENER, Barton Court, Colwall, Malvern.

IMPROVER.—Wanted, by a lad, age 17, a situation in a Gentleman's Garden—one where there is glass preferred.—G. COOPER, 9, Thorney Cottages, Iwer, Bucks.

IMPROVER.—Wanted, to place a youth under a good Gardener, where he may learn the Gardening-Premium given. Particulars to A. H., 17, Regent Street, Briton Ferry, Glamorganshire.

IMPROVER, under a Head Gardener.—Age 19, respectable; son of a Gardener. Has had three years' experience, principally under Glass.—A. E., 68, King's Road, Peckham, S.E.

IMPROVER; age 20.—Mr. F. FORD, The Gardens, Swalefish Park, Banbury, wishes to recommend a young man to a good Gardener, where he may learn to use Plasts, Nailing, Mowing, &c. Five years' experience; three years last place.

APPRENTICE, in a Gentleman's Garden or Nursery.—Age 18. Premium given, if required.—F. SPRAGG, Upton Grey, Odham, Hants.

COWMAN, or COWMAN and UNDER GARDENER.—Age 21; good character. Thoroughly understands Milkings.—J. DAVIES, 14, Lorne Cottages, Albert Road, Richmond, S.W.

TO HEAD GARDENERS.—ADVERTISER can with confidence recommend a really useful young man (Age 27), accustomed to general indoor work in a large establishment.—GARDENER, Bushey Grove, Watford.

TO GARDENERS.—ADVERTISER (age 28, single) seeks a situation in the Houses. Good Testimonials, Decorator, and Furnisher. Good references and testimonials.—POMONA, 17, Hermitage Street, Bath Road, Cheltenham.

TO GARDENERS.—Wanted, to place a respectable, well-educated lad, just on his fifteenth year, with a Nobleman's or Gentleman's Garden for two or three years. A small Premium would be given to a good kind man.—R. KEMP, Foulden, near Brandon, Norfolk.

TO NURSERYMEN.—THE ADVERTISER (Age 24), who understands the general routine of a Market Nursery, requires a situation. Four years' reference from last employer.—A. B., 92, Greenfield Road, West Green Road, Tottenham, Middlesex.

To Market Growers.

MANAGER; age 37.—To grow extensively Grapes, Peaches, Strawberries, Cucumbers, Tea Roses, &c. Good references.—G. H., The Hall Nurseries, Bushey.

NURSEYMAN, PROPAGATOR, GROWER, and SALESMAN.—ADVERTISER, active and energetic, and with thirty years' practical experience, seeks a situation, also a good Book-keeper, and can give first-class references.—HORIUS, 30, Foregate Street, Worcester.

MANAGER, TRAVELLER, or SHOPMAN.—Age 23; active and energetic; thirteen years' experience in good Houses. Thoroughly acquainted with every branch of the Seed Trade. Hundreds of references.—H. E., 29, Boscobel Gardens, Alpha Road, N.W.

CLERK, or HEAD SHOPMAN.—Age 38; twenty years' experience in the Seed and Nursery Trade; well acquainted with the routine of both. Efficient Correspondent and Book-keeper.—Y. Y. Z., *Gardeners' Chronicle* Office, W.C.

CLERK, or SHOPMAN.—Well acquainted with Book-keeping, Nursery and Retail Seed Trade.—S., 9, Hertfordbury Road, Hertford.

EPSS'S COCOA. GRATEFUL AND COMFORTING. "By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a pure, delicious, and invigorating beverage which may save us many heavy doctor's bills. It is the judicious use of such articles of diet that constitutes a more healthy and a more economical constitution; it is gradually built up until strong enough to resist every attack of illness which may befall us. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly-nourished frame.—*Cross's Swiss Milk*." Made simply thus, in bottles, labeled. Sold only in packets, labeled, JAMES EPSS AND CO., HOMEOPATHIC CHEMISTS, London. Makers of Epps's Chocolate Essent for Afternoon use.

HOLLOWAY'S PILLS.—Weak stomachs.—The distressing symptoms arising from enfeebled digestion are almost numberless, and of them can be readily dispelled by these admirable Pills. They clean the tutored tongue and remove all unpleasant tastes from the mouth, with flatulency and constipation. They give vigour to the stomach, liver, and every other organ, helping digestion to that healthy tone which fully enables it to convert all we eat and drink to the nourishment of our bodies. Hence, Pills are the surest strengtheners and the safest restoratives in nervousness, wasting, and chronic debility. Holloway's Pills are infallible remedies for impaired appetite, eructations, and a host of other disagreeable symptoms, which render miserable the lives of thousands of our fellow creatures. These Pills are approved by all classes

TO POTATO GROWERS and others.—About 15 cwt. of WOODSTOCK KIDNEY, for Seed. Cheap for Cash.
F. BATTARKE, Malpas, Cheshire.

MALLOW (*Malva moschata alba major*).

When we brought the Single Dahlias from oblivion, as it were, many laughed and said they must return from whence they came; yet, strange to say, with hardly a single exception they had favour with these very critics. Not only in England but in America and Australia, they are eagerly sought after. We may rely that they will never cease to be grown so long as the eye has a desire for beauty. J. Harvey, Esq., of Wilmington Hall, grows them extensively in tubs, and places them where desired, and as soon as the frost threatens they are removed to the conservatory, and continue blooming until Christmas, and the effect amongst the Chrysanthemums is both unique and beautiful.

The above will take a similar position with every lover of beauty, and be sought after by all, particularly those fond there are few exceptions) who admire a pure white flower with a dense green foliage. Its delicious fragrance will most assuredly bring this plant into the highest repute, and it will be seen by the engraving how very curious but elegant are its flowers, and when intermingled in cut blooms with the round shaped fluted flowers—and some are better adapted and last longer in water than, this—the contrast is beautifully pleasing, and, like the new Cactus Dahlia, only need to become a favourite. Being hardy it will grow in any ordinary border. For table decoration no flower is better adapted, and its beautiful Fern-like foliage lovely and valuable for garnishing dessert plates and dishes all the autumn; and to confirm its value the Floral Committee awarded a First-class Certificate on a small bunch of its flowers being brought before them.

2s. 6d. each; Seed, 2s. 6d. per packet.

Many that offer the POLYANTHUS, and issue peculiar drawings, probably never grow a named variety (old as it is), and are utterly unacquainted with its properties, which almost every exhibitor will confirm. Whereas we invite all to "Come and See" our Collection. Our seedlings are fast coming into flower, many of them are splendid; and the same with Primroses. Our "Harbinger" (of the latter) which was honoured with a First-class Certificate of the meeting of the Floral Committee of the Royal Horticultural Society, is now splendid, and surpasses anything in its class.

Seeds: *Polyanthus* and *Primroses*, from our Named Collection, 1s. and 2s. 6d. per packet.

HOSE-IN-HOSE POLYANTHUS.

This class for general garden decoration must become the order and fashion of the day for several important reasons: First, two flowers in the space of one, is of longer duration, and the diversity of colours may justly be compared to the Belgian Pansy; some of their tints are brilliant and quaint, and the variety of peculiar shapes they assume is surprising; some partake of the Jack-in-the-Green type, others Jackanapes on horseback, and Golligskitts, &c., which render them not only old-fashioned but favourites of former days, and cannot fail to be grown and become valued favourites in every border by everybody.

1s. 6d. and 2s. 6d. per packet.

NICOTIANA AFFINIS (True).

Nicotiana affinis is a most extraordinary plant:—Firstly, because so good a plant should be a Tobacco plant.—Next, because it is so different, both in growth and flowers, to the ordinary kind.—Thirdly, is because of its producing such splendid pure white noble flowers on long tubes, which renders it valuable for bouquets.—Fourthly, because it has such a delicious scent; in fact, it perfumes the whole surrounding atmosphere.—Fifthly, because its flowers fully expand at early evening and morning.

Its gigantic white Bivardi-like flowers have a most striking effect all the summer. It is beyond doubt the greatest novelty of the garden for 1882. In our nursery it was the amazement of all, and the result of several hundreds of packets of seeds being sold. It will unquestionably make a splendid Green-house Plant, and probably adaptable for Market-work. At night it emits its most agreeable fragrance, when its flowers are fully expanded; very free, and only attaining the height of a foot in any ordinary soil.

W. COLLINGFORD, Esq., introduced this splendid novelty, to whom all honour is due.

Figured and highly eulogised in *Gardener's Chronicle*.

Seed 2s. 6d.; Plants, in May, 1s. each.

For further particulars of all the above see H. C. & Sons' Catalogue.

H. CANNELL AND SONS,
THE HOME FOR FLOWERS, SWANLEY, KENT.

SPECIAL OFFER.—The undernoted may be relied upon as being unsurpassed in quality, having been saved under the personal superintendence of Mr. F. Smith, Esq., who has for 30 many years been famed for the production of the most perfect Florists' Flower Seeds:—**F. R. H. VERTEGANS, E. R. H. S., Chad Valley Nurseries, Birmingham.

NISBET'S VICTORIA TOMATO

This is a seedling from Vick's "Criterion," and for cultivating under glass or in the open air there is no Tomato can approach it for fruitfulness. The plant requires no stopping, as it keeps growing and fruiting in the greatest abundance. The fruit is pyriform, and grows in bunches, each bunch containing from eight to twenty fruit, which are the size and colour of a Victoria Plum. It contains but few seeds, and for flavour is unsurpassed.

By cultivating the Victoria Tomato there is no difficulty in obtaining a crop of Tomatoes ALL THE YEAR ROUND. The plant requires plenty of room and a rich loamy soil, with liberal applications of liquid manure. There is no fear of it producing a quantity of wood without fruit, as the bunches of fruit show at every joint; it needs no stopping, as it keeps growing and fruiting in the greatest abundance, and either for cultivating under glass, or in the open air, it surpasses all others for fruitfulness.

To grow it in the greatest perfection a few of the many bunches should be removed and the fruit thinned out a little. This will produce fine, large, handsome fruit.

"The Original Plant is growing, under glass, at Aswarby, covering a space 15 feet by 6 feet, and at the present time is carrying a crop of 600 bunches of fruit, as many more having been gathered from it during the summer."
"August 30, 1879. "RICHARD NISBET, Gardener, Aswarby Park."

GOLDEN TANKARD MANGEL.

WE HAVE A SPECIALLY FINE STOCK OF THE ABOVE, GROWN ON OUR OWN SEED FARMS, TO OFFER TO THE TRADE.

PRICE ON APPLICATION.

A SEED LIST

ILLUSTRATED

and as full as can be desired of useful and reliable information on Garden and Flower Seeds, yet without any unnecessary costliness, post-free on application. Such a catalogue as this is claimed to be must of necessity conduce to economy, both as regards purchaser and vendor.

In addition to the well known and trusty favourites in Seeds, the

BEST NOVELTIES

are included, but unproved and excessively expensive kinds are omitted.

Every endeavour is made to supply Seeds of the *Finest Quality and of the Best Varieties at a Moderate Price*, to attain which desirable object neither trouble nor expense are spared in the procuring and proving of the Seeds.

THE GUINEA COLLECTION

(Carriage free), for the Amateur's Garden, has been much approved, and contains a most valuable and useful assortment of Equable Seeds.

All Vegetables are gladly and promptly attended to.

WILLIAMS' NEW HOTHOUSE SHADING.

The most suitable for Shading Orchids, Ferns, Palms, Stove and Greenhouse Plants.

The only kind of shading used at the Victoria Nurseries. It is a strong durable Netting, woven in squares, so close as to exclude the direct rays of the sun, but admitting the greatest amount of light attainable through shading. It withstands the weather better than any other class of Shading, and, on account of the thickness of its texture, it may be very beneficially used during cold weather to keep out the frost.

BLINDS MADE UP AND FIXED COMPLETE.

Sold in Pieces, 30 yards long by 1½ yard wide. Price, 45s. each.

B. S. WILLIAMS,

VICTORIA and PARADISE NURSERIES, UPPER HOLLOWAY, LONDON, N.

CATLEYA AMETHYSTOGLOSSA.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on WEDNESDAY, March 15, at half-past 12 o'clock precisely, by order of Messrs. HUGH LOW & CO., very fine imported plants, in the best possible condition, of the rare and lovely CATLEYA AMETHYSTOGLOSSA, amongst them several grand masses of unusual size. This Cattleya is the finest of the section of the genus to which it belongs, and some idea of its beauty may be formed by an inspection of a plant which will be on view, which has produced upwards of thirty flowers on a spike. At the same time will be offered imported plants of CATLEYA AGLANDLIE, and other choice ORCHIDS; also 100 established plants of PHALÆNOPSIS SCHILLERIANA, &c., the majority in bud or flower.

On view the morning of Sale, and Catalogues had.

AUCTION ROOMS AND OFFICES, 38, KING STREET, COVENT GARDEN, LONDON, W.C.

THURSDAY NEXT.

PHALÆNOPSIS TETRASPIS.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., by order of Messrs. SANDER, on THURSDAY NEXT, March 16,

A Consignment of the above New Phalænopsis, Now offered for the first time.

In habit it is like VIOLACEA, but the flowers are pure white, produced in quantity on spikes, and so sweet-scented are they that a very few flowers will perfume a whole greenhouse.

On view the morning of Sale, and Catalogues had.

AUCTION ROOMS AND OFFICES, 38, KING STREET, COVENT GARDEN, LONDON, W.C.

WM. CLIBRAN & SON, OLDFIELD NURSERY, ALTRINCHAM.

SEND FOR A PRICE LIST OF

JOHN BLAKE'S PATENT SELF-ACTING HYDRAULIC RAMS,

*For Raising Water for the Supply of Towns, Villages, Irrigation, Railway Stations, Mansions,
Fountains, Farms.*

No cost for Motive Power, which is obtained from the Stream of Water passing through the Rams.

NO OILING OR PACKING REQUIRED.

Made in sizes to raise from 300 to 500,000 Gallons per day. Will Force to a Height of 1500 feet.

Special Rams for High Falls to send up Two Gallons out of every Five Gallons passing through them.

APPLICATION OF BLAKE'S PATENT HYDRAULIC RAM B.

This Ram is worked by impure river water, whilst pumping pure water from a well and forcing it to a small reservoir on the hill, at an elevation of 295 feet, and a distance of 1 mile, from which reservoir the water is gravitated for fire extinguishing and general requirements of Mansion, Stables, Farm, and Village.

TESTIMONIALS.

From Mr. WILLIAM LAIT, County Surveyor, Compton Fenner, Watton & Watney 16, 1881.—"I have much pleasure in stating that the Patent Hydraulic Ram I had from you for the Rev. J. Cardwell-Gardner, of the Vicarage, Butlers Marston, is, I consider, remarkably successful, as indicated below. 4120 gallons of water per day are passing through the Ram with a descent of 13 feet 8 inches; out of this small quantity, 1020 gallons are sent up to a height of 41 feet; showing 75 per cent of useful effect; and the noise of its working is so slight as to be almost inaudible.

From V. F. BENNET-STANFORD, Esq., M.P., Pyt House, Tabery, Wilts, August 20, 1880.—"I have no hesitation in saying your Self-acting Hydraulic Ram and Apparatus for Extinguishing Fire, which you laid down here, including about 1 mile of pipes, are very satisfactory. The Ram forces upwards of 5000 gallons per day to a service reservoir, holding 25,000 gallons at an elevation of 295 feet, being 70 feet above the roof of the house, from which reservoir the water is distributed to the house, stables, home farm, and several cottages; and, in case of fire, four jets can be thrown on to the house from different sides at a great force and large volume. I consider the work has been done well and efficiently, and does you credit."

From the Right Hon. the Earl of GRANARD, Castle Forbes, March 11, 1880.—"The Hydraulic Ram, erected for me at Castle Forbes has answered perfectly. Considering the very small fall attainable by the nature of the ground, it is a great success, and throws up water to a cistern on the top of the tower 80 feet high. When Mr. Blake first proposed to put it on I doubted the possibility of its succeeding, owing to the nature of the ground, but I have been most agreeably undeceived."

From T. H. STODDERTON, Esq., Etherow House, Hindfield, February 29, 1879.—"Induced by the good report of my cousin, Mr. T. A. Siblebottom, as to the working of the Hydraulic Ram he had from you, I ordered the one you fixed here a year ago, which I am pleased to say has since worked well night and day. Yet the two Rams you fixed at SNOW'S Hill Manor, Gloucestershire, for my brothers and myself, are I think a still more remarkable example of your success. We had a Ram fixed by a well-known firm, which proved a miserable failure, and which your Rams displaced. They are forcing the water through $\frac{3}{4}$ of a mile of delivery pipe, a little in excess of the quantity you guaranteed to an elevation of 320 feet, and without the slightest hitch to the time of the last report from our tenant."

From the Right Hon. the Earl of ROSMERE, 56, Eaton Place, S.W., June 12, 1880.—"Sir,—In reply to your inquiry, I have pleasure in stating that the Hydraulic Ram which you erected for me at Gayton, does its work remarkably well, and is a great success. I think the work is especially creditable to you on account of the very small fall of but 3 feet with which you had to deal, and I shall always be glad to recommend you.—Yours faithfully, ROSMERE."

From Sir ROBERT MENZIES, Bart., of Menzies, Rannoch Lodge, Rannoch, August 20, 1880.—"The Hydraulic Ram you fixed for me to supply water to Rannoch Lodge and Camessack, two houses $\frac{1}{2}$ mile apart, is a complete success. The extreme distance the water is carried is $\frac{1}{2}$ mile, and, though the elevations of the two houses are different, there is a regular supply of 7 quarts per minute to each house, which has never ceased since the Ram was set a-going, about three months ago. Your Ram took the place of one previously tried on the same spot, and which did not succeed, and was in fact a complete failure."

From CHAS. C. CARL, The Cray Fisheries, Foot's Cray, Kent, March 30, 1881.—"In reply to inquiry as to my opinion of the Patent Hydraulic Ram you fixed here, I may say that it has displaced two Rams by a reputed maker, which were so unsatisfactory that I put down a live-steam engine and pump, but this being a continual expense and trouble, I resolved to try your Ram, and am happy to say that my best hopes have been more than realized. The quantity of water sent up by the Ram is abundantly in excess of what I need to keep the Fisheries in perfect health, and this without any trouble."

From J. SPENDER CLAY, Esq., Ford Manor, Lingsfield, Surrey, August 6, 1880.—"In reply to your letter of enquiry I am glad to be able to say that the two Hydraulic Rams which you fixed here are working satisfactorily, and that out of 13 gallons 3 quarts per minute, the maximum yield of the spring, they deliver to the top of my house, distant a full mile from the spring, 4 gallons 1 quart per minute, or 620 gallons per twenty-four hours, being 120 gallons above the quantity you guaranteed."

From Captain GANDY, Castle Bank, Appleby, February 11, 1880.—"The Self-acting Hydraulic Ram you erected for me is an excellent example of strength and good workmanship. Whilst working with 3 feet 4 inches fall it forces water 73 feet high, and so far gives me every satisfaction. It will do more work in one day than the old Ram of another make could do in a week."

From Captain TOWNSEND, Winclean, February 10, 1877.—"In answer to your inquiry I am glad to say the Hydraulic Ram you sent me in November, 1875, is working exceedingly well, and gives no trouble. It will work when quite immersed, as it has been several times during the floods this winter, forcing up water through a delivery pipe 900 yards long at the rate of 82,000 gallons per day, although you only promised 50,000."

JOHN BLAKE, Engineer, ACCRINGTON, LANCASHIRE.

WILLIAMS' PRIMULAS AND CYCLAMENS

THE **Gardeners' Chronicle.**

SATURDAY, MARCH 11, 1882.

PLANTS OF POETRY AND FANCY.

A PERSON who dearly loves flowers, as many humble folk do, counted with surprise the various blossoms in her garden and upon the cottage wall on Christmas Day. Lists of flowers out of season—though a flower can never be ill-timed—have been often given by those who have noted them. Staying long or coming early—who can say which in a season when the Rose, and not the Christmas Rose, blossoms in mid-winter?—the Primrose, Snow-drop, Anemone, and Crocus might not have surprised us in a well sheltered garden, but beside the cottage porch the "summer's queen" showed both blossoms and promising buds on Christmas Day.

The poets are the best observers of Nature's good old fashions, and they have never described the Rose as a winter flower. Burns says

"Mild be the sun on this sweet blushing flower,
To the gay rosy morn as it bathes in the dew."

These words breathe of summer! And in the "Legend of the Rose," when the Rose tree itself relates the story of the origin of its thorns, the period of the event is clearly summer. Says the Rose—

"Young Love, rambling through the wood,
Found me in my solitude,
Bright with dew and freshly blown,
And trembling to the zephyr's sighs."

He stooped to the flower to sip, when a bee flew out and stung his lip, and off flew Cupid to his mother. She, to please her boy, strung his bow with bees, from which she had first removed the stings.

"And none since that eventful morn
Have found the Rose without a thorn."

But this winter has been exceptional, and it should be known in all countries where the Rose is met with—that is, throughout the northern hemisphere both in the Old World and the New, from Siberia to Bengal, from Northern Europe to Africa, from Lake Winnipeg and Hudson's Bay to Mexico—that the Rose blossomed on a cottage wall in Sussex on Christmas Day last year. "And what if it did?" says some morose person of purely commercial mind, busy perhaps just now, but destined to regret some day that flowers and gardens and simple tastes yield him no pleasure, and that all the world for him is as void as an empty eggshell. Bless all flowers, trees and plants of every kind, including Toadstools and fungi, especially those which are edible. Bless all floral fancies, legends and languages—all superstitions, errors and absurdities connected with plants—all heraldic badges, and emblems taken from the vegetable world, especially the Rose, the Thistle, and the Shamrock—all sacred trees and plants, such as the Deodar and the Pecup, the Oak and Orchis spotted at Gethsemane, and others, plucked and put in royal bouquets, or in humble garlands and posies worn in caps or button-holes! Bless them!—erect or trailing, climbing, creeping, twining, tall like the Palm, or lowly as the Daisy, sleeping or waking, bless them all!

This invocation and the appearance of the early flowers may remind us of several floral and monkish symbols of religious festivals. A good Franciscan father loving flowers and observing the time of their appearing, invented a useful "timepiece" which, if it did not strike, blossomed with some regularity at about the period when the festivals recurred. The arrival of the pure Snowdrop, white and drooping, reminded the good priest to light the taper to the Virgin, at Candlemas, February 2; the Lady's Smock and the Daffodil ushered in the Annunciation, March 25; the Blue Bell the festival of St. George; the Ranunculus may remind the devout of the invention of the Cross. The scarlet Lychnis arrives about the date of St. John the Baptist's Day or thereabouts; the white Lily at the time of the Visitation of Our Lady, July 2; and the Virgin's Bower at her Assumption, August 15. On the same monkish authority we learn that the section of the stem of the Bracken bears, not the marks of pagan Oak or Roman eagle, as they may seem to some, but a distinct tracing of the sacred letters, I.H.S.

The catholicity of floral tokens, and the antiquity of their use as religious offerings may be recognised in the customs of all Churches; and even now, though superstitious usages are happily on the decline, yet floral decorations are still thought appropriate. Exactly the same flowers that were dedicated to Juno and Diana and to the northern Freya and Bertha, were afterwards devoted to the shrines of the Virgin Mary. The Lily and all white flowers were typical of the Virgin's purity, and the flowers of Diana—humble plants generally, growing in unfrequented glens and shaded dells, unvisited by man—were piled on the mediæval shrines of "Mary," with the same idea of their freedom from human taint. Among our native Mary's flowers were the Cost-Mary (*Balsamita vulgaris*), King Cup, Marsh Marigold, or "winking Marybud with golden eye," a very desirable talisman for the pocket in some companies, for it prevents angry words from being addressed to its possessor. Another Mary-gold, not the *Caltha palustris* just referred to, but the *Calendula officinalis*, was honoured like the above, as its name indicates; while Our Lady's Mantle possessed what some would regard as the divine quality of bringing to those who placed it under their pillow sound and sweet repose. Our Lady's Ded-straw, *Galium verum*, was taken as the plant on which the infant Jesus was laid in the manger, and in a painting of the Nativity, by N. Poussin, this "straw" is represented; and the spell attaching to it has rendered it, in France, with the superstitious, a specific against epilepsy to this day.

Since we are among the fancies of mediæval times another odd conceit of the same sort and date may be noticed in the white marks which spot the green leaves of Our Lady's Thistle, *Silybum Marianum*, where drops of the Virgin's milk fell on them. Several plants in classic story were as oddly stained, as the Rose when Venus pricked her foot, or the same flower when Cupid split the cup of nectar.

There are other plants dedicated by devout Roman Catholics to the Virgin, such as the Cuckoo-flower, otherwise called Our Lady's Smock—

"All silver white,
Which paints the meadows with delight."

Shakspere used a little licence here, for the Cardamine pratensis is nearer lilac than white in colour; perhaps he referred to *C. amara*, which grows in meadows in masses white as linen sheets laid out to bleach. Without exhausting the long list of Mary's flowers, we may just mention in quick succession, Our Lady's Cushion, Our Lady's Fingers, Our Lady's Tresses, her Slipper, Seal, and Hair; also the "Fair Maid of February," the Snowdrop, a

flower of earliest coming whose appearance touches all hearts and awakens pure aspirations, such as Tennyson interpreted in lines of great beauty:—

"Make Thon my spirit pure and clean,
As are the frosty skies;
Or the first Snowdrop of the year
That in my bosom lies."

Perhaps we should explain that Our Lady's Seal is the Black Briony; Virgin's Hair is the Quaking Grass. Flowers of more pomp and presence, dedicated to the Madonna, were the blossoming Almond, the white Iris, white Lily, and Narcissus. She has been herself called the Lily, as by Keble, in the lines beginning:—

"Ave Maria!—blessed maid!
Lily of Eden's fragrant shade."

From the Virgin's tears sprang Lilies of the Valley, in imitation of several flowers as

FIG. 46.—LYGOCHEITON FORSTERI, SHOWING HAIR.

strangely created among Greeks or Romans. Io's breath first called forth the Violets, and others came as suddenly at the wish of gods and goddesses, like the Narcissus, in full bloom.

The "Hail Mary!" of the verses just repeated, leads us to mention in conclusion the "Devotion of the Rosary of the Blessed Virgin Mary;" and the Rosary, the book of the unlettered, belongs to our subject, because it was originally—or at least frequently—a string of beads made of Rose leaves tightly pressed in moulds, and sometimes of Roses strung together. The Turkish and Buddhist Rosaries had 99 and 108 beads, and that of the Mohammedans had also 108 beads, a number corresponding to the number of sins possible to the Mohammedans, and to the prayers proper to be repeated daily. *H. E.*

THE LEE, Blackheath, and Lewisham Horticultural Society's Summer Show is to be held on June 28 and 29.

New Garden Plants.

ERIA VITTATA, Lindl.

THIS species has oblong cylindrical or oblong fusiform bulbs with some furrows, and reaches 4—5 inches in length. The two leaves are more than membranaceous, verging to thin fleshy, being very soft, as in *Eria stellata*. The shape is cuneate oblong-lanceolate acute. The lateral raceme is not many flowered. The green hairless flowers have the sepals, petals, lip, and even the column adorned with red stripes. The oblong crenulate lip has five plaited lamellæ, which are edged with red. The column has a square projection on each side. The flowers are equal in size to those of *Eria profusa*, Lindl. This is a most remarkable curiosity from a botanical point of view. Till now the plant was only known from Cathcart's drawings, prepared in Sikkim Himalaya by Indian artists, and lent by Sir J. (then Dr.) Hooker to Dr. Lindley, who described the plant from the drawing in his second *Contributions to Indian Orchidology*. I feel quite persuaded that the plant at hand is the same as that described, for it corresponds in all details. The glorious dense inflorescence, however, which makes one think of *Saccolabium Blumei*, may be the product of an exaggerated phantasy, perhaps in consequence of a smoke of opium!

I am indebted for good materials to Messrs. Veitch, who tell me they had them from Mrs. Russell Sturgis' garden, at Grove Farm, Leatherhead. A great discrepancy exists in the statement that the plant was of Cingalese origin. I do not think this can be correct. It may, indeed, have been sent by somebody who grows Orchids in Ceylon. The indications of locality sent by possessors of collections of Orchids must be looked at with great caution. Recently *Cymbidium longifolium*, Don, *Galeandra Baueri*, Lindl., *Phaius Tankervillei*, Bl., came to my hands—all reported as coming from Madagascar, in lieu of Himalaya, Mexico, China. Many such instances might be recorded. *H. G. Rehb. f.*

DULBOPHYLLUM CUPREUM (Lindl.) FLAVUM.

A variety with light yellow flowers instead of the red ones. It was sent by Messrs. J. Veitch & Sons, who obtained it from Mr. James Routledge, gardener to C. L. Wood, Esq., Freeland House, Bridge of Earn. *H. G. Rehb. f.*

EPIDENDRUM CINGILLUM, n. sp.*

A botanical curiosity. An *Epidendrum* with thin, very strong stems, the branches at hand shorter than a span. The five leaves are grassy, measuring 3 inches in length, by 3—4 lines in width. The few-flowered raceme of ochre-coloured flowers has lanceolate bracts nearly equalling one-third of the stalked ovary. Sepals and petals linear-lanceolate, the former a little broader. The lip is very curious. It is much broader at the base and cordate, much narrower towards the fore part and retuse. There are two semilunar orange calli at the base, the median vein is keeled a little, and there is a kind of semilunar line around the keel consisting of dark purple spots. The column has at the top some sordid mauve spots. The flower is equal in extent to the smaller flower of an *Epidendrum inversum*. It was sent by Messrs. J. Veitch & Sons, but it came into their hands from Mr. Parr, gr. to Mrs. Russell Sturgis, Grove Farm, Leatherhead. *H. G. Rehb. f.*

PHALENOPSIS SCHILLERIANA VAR. VESTALIS,
n. var.

As we are not rich in grand novelties, there is a very pronounced tendency to break up the immense masses of some species into varieties. There is a great difficulty in avoiding hairsplitting, and the practice of naming individual plants whose differences are so slight, that the next individual may break down the

Epidendrum cingillum, n. sp.—*Epidendrum caulis teretibus rigidibus ramosis; foliis in caule ad 3 membranaceis lanceolatis obtuse acutis; racemo foliis breviori paniculato; bracteis linearisetosis acutis ovaria pedicellata longe non exarquantibus; sepalis linearisetosis acutis; tepalis linearibus; labello adnato cordato utrinque constricto subquadrate, antice bene retuso, callo semilunari utrinque auto basini, carinae elevatius terminis antepositis, lateralibus tamen obscurissimis. Flos ochraceus illi *Epidendri inversi* parvis subæqualis. Labelli calli aurantiaci circumdati linea cingillari macularum rubrarum. Columna: venter maculis sordide violaceo-purpureis. Ex hort. Veitch. *H. G. Rehb. f.**

character, or whose flowers in the next season may present just the same claim for new names, though indeed they may be borne on the same plant. There have been very trustworthy observations as to this point, since the exposition to light, air, heat, have decided influence on the intensity of colour, and even the markings. An immense difficulty results from the interest of importing firms who do not care to let the origin of their plants be known to their dear fellow-workmen, as they may show a decided inclination to hunt upon the grounds of their competitor. If we could watch the importations geographically, we might enjoy many a success we lack now. I have explained my views about this in a memorandum about *Cattleya labiata* Percivaliana which may appear one day in these columns. It is provoking to be urged to name a single flower of a *Cattleya* of the labiata group. Some help might be given as to geographical statements. I am pleased to have before me the inflorescence, and at the same time the water-colour sketch (prepared by Mr. Henry G. Moon, of Stamford Hill) of a white *Phalenopsis Schilleriana*.

the plant. I have carefully dried the glorious flower, so that such of my English visitors who may have a Thomasian sceptic feeling may see and state the truth of my assertions. I feel quite persuaded that Mr. Stuart Low stands now in a grave dilemma. For helping Orchidists he has either to send a traveller afresh to fetch new individuals, or he may deliver to his fellow workmen a speech at Mr. Stevens' about the exact details of the habitat—perhaps his maiden speech in this line. *H. G. Rehb. f.*

FREESIA LEICHTLINII MAJOR.

We have been favoured by Messrs. Charles Smith & Son, Caledonia Nursery, Guernsey, with some very fine cut blooms of the charming *Freesia refracta* alba, and of a hybrid between that plant and *F. Leichtlinii*, for which they propose the name of *F. Leichtlinii major*, the flowers being as large as those of *F. refracta* alba, and much larger and stronger than those of the typical *F. Leichtlinii*. The colour of the flower is pale cream, the lower segment having at its base a blotch of bright orange. The base of the tube

J. Smith separated it as a distinct genus. Unfortunately the character of the venation is hardly perceptible on a superficial glance, and is not represented in the figure.

The plant is a native of the Polynesian Islands, and is therefore not so hardy as the North American and Japanese species commonly cultivated. The plant is not new to gardens, but is much less frequently seen than its merits justify.

SEASONS OF SHAKSPERE'S PLAYS.

REV. H. N. ELLACOMBE has collected for the Shakspeare Society a number of references giving incidental evidence as to the season of the year in which the action in sundry of the plays was supposed by the author to take place. It is obvious that, except in certain special cases, this is not a matter of any great importance, but sometimes it is so, and never is it devoid of interest. Mr. Ellacombe has

FIG. 47.—LYGODICTYON FORSTERI: BARREN AND FERTILE FRONDS WITH SPORES, VENATION RETICULATE.

Every one of us might have guessed its occurrence; but, as I believe, no one had hitherto seen it. It is now before us in Messrs. Low & Co.'s glorious collection of *Phalenopsis*. If there is no artistic liberty in the drawing, then it is a great recommendation of Mr. Low's management, since there is an immense difference between the very small first leaf and the fine last one. Orchids are very eloquent. They tell their master, by their appearance, how they are treated. They praise a good grower, and they resent the careless behaviour of would-be gardeners who neglect those lovely ornaments of tropical paradises. *H. G. Rehb. f.* [We learn from Messrs. Hugh Low & Co., that the leaves of the *Phalenopsis* are accurately represented, as regards size, in the drawing referred to by Professor Reichenbach. Ed.]

PHALENOPSIS STUARTIANA, Rehb. f.

Mr. Norman C. Cookson, Oakwood, Wylam-on-Tyne, has kindly sent me a flower that surpasses the finest wild-grown flowers I had from Mr. Stuart Low, and which equals that of a very good *P. amabilis* flower. Such news may stimulate the demand for

is also of a yellow colour. Like the white-flowered species, the flowers are fragrant.

ODONTOGLOSSUM PISCATOREI FLAVEOLUM.

This is a highly curious variety, with very blunt oblong petals. There is some sulphur on all parts of the perigone. It was sent by Messrs. J. Veitch & Sons.

LYGODICTYON FORSTERI.

At one of the recent meetings of the Floral Committee considerable interest was occasioned by the exhibit of a plant of this desirable climbing Fern. As will be seen by the illustrations now given (figs. 46, 47), the plant has entirely the habit of the species of *Lygodium*, and is suitable for growing on pillars, or on rock-work in a warm fernery. The general character of the foliage is more handsome than that of the species of *Lygodium* generally, and as it is of fine growth it is preferable to them on the ground of effectiveness. The barren and fertile fronds vary considerably in appearance, as may be seen in our drawing. From *Lygodium* the present plant differs particularly in its much more branched venation, on which account Mr.

naturally sought for indications in the mention of flowers and fruits, and prefaces his paper by a complete list of plants mentioned in each play. Mr. Ellacombe admits that his results are not directly of importance, but he very truly adds, as may be done with every piece of honest work, that the value of the research is not to be measured by the visible results at the moment, for it is certain that at some time or another the utility of genuine work will become manifest. In the present case Mr. Ellacombe tells us that the inquiry has confirmed his previous opinion, "that even in such common matters as the names of the most familiar everyday plants Shakspeare does not write in a careless haphazard way, naming just the plant that comes uppermost in his thought, but that they are all named in the most careful and correct manner, exactly fitting into the scenes in which they are placed, and so giving to each passage a brightness and a reality which would be entirely wanting if the plants were set down in the ignorance of guess-work. Shakspeare knew plants well, and though his knowledge is never paraded, by its very thoroughness it cannot be hid."

As an illustration of the manner in which Mr. Ellacombe has executed his self-imposed task we may

quote what he says with regard to *Mitsunomia Night's Dream*:—

"The name marks the season, and there is a profusion of flowers to mark it too. It may seem strange to us to have 'Apricocks' at the end of June, but in speaking of the seasons of Shakspeare and others, it should be remembered that their days were twelve days later than ours of the same names; and if to this is added the variation of a fortnight or three weeks, which may occur in any season in the ripening of a fruit, 'Apricocks' might well sometimes be gathered on their summertime day. But I do not think even this elasticity will allow for the ripening of Mulberries and purple Grapes at that time, and scarcely of Figs. The scene, however, being laid in Athens and in Fairyland, must not be too minutely criticised in this respect. But with the English plants the time is more accurately observed. There is the 'green corn'; the 'Dewberries,' which in a forward season may be gathered early in July; the 'Jush Woodbine' in the fulness of its business at that time; the 'Pansies,' or 'Love in Idleness,' which (says Gerard) 'flower not only in the spring, but for the most part all summer thorow, even until autumn;' the 'sweet Musk Roses and the Eglantine,' also in flower then, though the Musk Roses, being rather late bloomers, would show more of the 'Musk Rosebuds' in which Titania bid the elves 'Kill cankers' than of the full-blown flower; while the Thistle would be exactly in the state for 'Monsieur Chouwhet' to 'kill a good red-lipped humble bee on the top of it' to 'bring the honey-bee' to Bottom. Besides these there are the flowers on the 'bank whereon the wild Thyme blows; where Oxslips and the nodding Violet grows,' and I think the distinction worth noting between the 'blowing' of the wild Thyme, which would then be at its fullest, and the 'growing' of the Oxslips and the Violet, which had passed their time of blowing, but the living plants continued 'growing.'"

PYRETHRUM INSECT-POWDER.

(Concluded from p. 297.)

APPLICATION OF PYRETHRUM IN FUMES.—The powder burns freely, giving off considerable smoke and an odour which is not unpleasant. It will burn more slowly when made into cones by wetting and moulding. In a closed room the fumes from a small quantity will soon kill or render inactive ordinary flies and mosquitos, and will be found a most convenient protection against these last where no mosquito bars are available. A series of experiments made under our direction indicates that the fumes affect all insects, but most quickly those of soft and delicate structure.

This method is impracticable on a large scale in the field, but will be found very effective against insects infesting furs, feathers, herbaria, books, &c. Such can easily be got rid of by enclosing the infested objects in a tight box or case, and then fumigating them. This method will also prove useful in green-houses, and, with suitable instruments, we see no reason why it should not be applied to underground pests that attack the roots of plants.

ALCOHOLIC EXTRACT OF PYRETHRUM POWDER.—The extract is easily obtained by taking a flask fitted with a cork and a long vertical glass tube. Into this flask the alcohol and Pyrethrum are introduced and heated over a steam-tank or other apparatus. The distillate, condensing in the vertical tube, runs back, and at the end of an hour or two the alcohol may be drained off, and the extract is ready for use. Another method of obtaining the extract is by reprecipitation, after the manner prescribed in the American Pharmacopœia. The former method seems to more thoroughly extract the oil than the latter; at least, we found that the residuum of a quantity of Pyrethrum from which the extract was obtained by reprecipitation had not lost a great deal of its power. The first method is apparently more expensive than the other, but the extract is in either case more expensive than the other preparations, though very conveniently preserved and handled.

The extract may be greatly diluted with water, and then applied by means of an atomiser. Prof. E. A. Smith, of Tuscaloosa, Ala., found that, diluted with water at the rate of one part of the extract to 15 of water, and sprayed on the leaves, it kills cotton-worms that have come in contact with the solution in a few minutes. The mixture in the proportion of one part of the extract to 20 parts of water was equally efficacious; and even at the rate of 1 to 40 it

"If the rate of Mr. Galt's (see, p. 29) is to be strictly limited to Blue-Boy, the use of a *Mitsunomia Night's Dream* does not apply. The difficulty can only be met by supposing the scene to be laid at any night in May, even in the last night, which would coincide with our 12th of June."

kills two-thirds of the worms upon which it was sprayed in 15 or 20 minutes, and the remainder were subsequently disabled. In still weaker solution, or at the rate of 1 to 50, it loses its efficacy, but still kills some of the worms and disables others. Prof. Smith experimented with the extract obtained by distillation, and another series of experiments with the same method was carried on last year by Prof. R. W. Jones, of Oxford, Miss. He diluted his extract with twenty times its volume of water, and applied it by means of an atomiser on the cotton-worm and the boll-worm with perfect success. Mr. E. A. Schwarz tried last summer the extract obtained by reprecipitation, and found that 10 drachms of the extract, stirred up in 2 gal. of water and applied by means of Whitman's fountain pump, was sufficient to kill all cotton-worms on the plants. Four drachms of the extract to the same amount of water was sufficient to kill the very young worms.

PYRETHRUM IN SIMPLE WATER SOLUTION.—So far as our experiments go this method is by far the simplest, most economical, and efficient. The bulk of the powder is most easily dissolved in water, to which it at once imparts the insecticide power. No constant stirring is necessary, and the liquid is to be applied in the same manner as the diluted extract. The finer the spray in which the fluid is applied the more economical is its use, and the greater the chance of reaching every insect on the plant. Experiments with Pyrethrum in this form show that 200 grains of the powder stirred up in 2 gal. of water is amply sufficient to kill the cotton-worms, except a very few full-grown ones, but that the same mixture is not sufficiently strong for many other insects, as the boll-worm, the larva of the *Terias nicippe*, and such species as are protected by dense long hairs. Young cotton-worms can be killed by 25 grains of the powder stirred up in 2 quarts of water.

The Pyrethrum water is most efficacious when first made, and loses power the longer it is kept. The powder gives the water a light greenish colour, which after several hours changes to a light brown. On the third day a luxuriant growth of fungus generally develops in the vessel containing the fluid, and its efficacy is then considerably lessened.

THE TEA, OR DECOCTION.—Prof. E. W. Hilgard, of Berkeley, Cal., is the only one who has experimented with Pyrethrum in this form, and he expresses himself most favourably as to the result. He says:—

"I think, from my experiments, that the *tea*, or *infusion*, prepared from the flowers (which need not be ground up for the purpose) is the most convenient and efficacious form of using this insecticide in the open air; and that it is used at times when the water will not evaporate too rapidly, and that it is applied, not by pouring over in a stream, or even in drops, but in the form of a spray from a syringe with fine holes in its rose. In this case the fluid will reach the insect despite of its water-shedding scales, hairs, &c., and stay long enough to kill. Thus applied I have found it to be efficient even against the armoured scale-bug of the Orange and Lemon, which falls off in the course of two or three days after the application, while the young brood is almost instantly destroyed. As the flower tea, unlike whale soap and other washes, leaves the foliage perfectly clean, and does not injure even the most tender growth, it is preferable (at that score alone) and in the future it can hardly fail also to be the cheaper of the two. This is the more likely as the tea made of the leaves and stems has similar, although considerably weaker, effects; and if the farmer or fruit grower were to grow the plants, he would save all the expense of harvesting and grinding the flower-heads by simply using the header, curing the upper stems, leaves, and flower-heads all together, as he would Hops, making the tea of this material by the large boiler, and distributing it from a cart through a syringe. It should be diligently kept in mind that the least amount of boiling will seriously injure the strength of this tea, which should be made with briskly boiling water, but then simply covered over closely, so as to allow only a little evaporation as possible. The details of its most economical and effective use on the large scale remains, of course, to be worked out by practice."

The method of applying Pyrethrum in either of the three last-mentioned forms is evidently far more economical in the open field, and on a large scale, than the application of the dry powder, and, moreover, gives us more chance of reaching every insect living upon the plant to which the fluid is applied. The relative merits of the three methods can be established only by future experience. C. V. Riley, in "American Naturalist."

* *American Entomologist*, vol. iii., pp. 255, 259.

† From 1 lb. of the powder 1 pint of extract was made, each drop of the extract representing 1 grain of the powder. The actual cost of making the extract was 5 cents.

ORCHIDS AT OAKLANDS.

ONE is so accustomed to read accounts of the largest collections of Orchids in the country that it may not be amiss to offer some remarks on a collection which I have many times had the pleasure of inspecting at different periods—a collection which may not be noted for the quantity of plants grown, but certainly for the quality or varieties under culture. It has seldom been my good fortune to see finer cool Orchids grown than those in Mr. Allan Edwards' collection at Oaklands, Dawlish. Many people would grow Orchids but who hesitate for fear of not having suitable houses; the general idea is you must have at least four or five houses. This is quite a mistake, as numbers of small collections in the country prove. Here the cool-house is a low span with path up the centre and stages on each side; on these is spread small coal, and on this stand the pots. The plants are all close to the glass—an important point. This house is heated by a single flow and return pipe. There are ventilators 1 foot apart right round the house, fixed in the brick-work.

Now for the plants. A more healthy and finer looking lot of cool Orchids it is impossible to see anywhere; leaves thick and leathery, not a speck of dirt on them; bulbs in every case far exceeding in size the imported ones, which is saying a good deal. As to varieties of *Odontoglossum crispum* to be seen here I can only say that the finest only are grown; as each plant flowers for the second time, and is found to be below the standard, it is at once weeded out, so that only the finest formed flowers are here to be seen—those with large sepals and petals almost overlapping, and forming, as it were, a square. Some are much spotted with dark brown, others with spots of a purple tint, others highly suffused with pink, others pure white. Here are also several fine plants of *Lycaste Skinneri* of different colouring, among them the rare *Lycaste Skinneri alba*; *Oncidium macranthum hastiferum*, *O. Pescatorei*, blocks hanging with *Cattleya citrina*—among these a plant which has never been taken off the branch upon which it was found growing in its native home, and which annually sends down two flowers on one stem from each bulb made; *O. Rossii*, very strong, and doing well; several of *O. nebulosum*—one especially was the finest for size and quality of flower that I have seen. *Dendrobium Jamesianum* seemed to be quite at home here, as were *Masdevallias*, among them "bull's blood var.," of Harr yana. *O. cordatum*, the finest variety, to which Mr. Sander made reference in the *Gardeners' Chronicle* of July 3, 1880, and which last year had over forty flowers on the spike.

The next is the *Dendrobium*-house, containing a grand lot of the favourite *D. noble*, *D. Wardianum*. The flowers on one superb variety were found to be 4 inches across. Near it hung the old and original variety, now so scarce, also *D. Ainsworthii*. Several *D. Cambridgeanum*—one plant a mass of deep golden flowers; many *D. formosum giganteum*, *D. chrysanthum*, *D. chrysotoxum* and var. *superbum*, *D. thyrsoiflorum*, *D. densiflorum*, one plant of which carried last year thirty odd spikes; *D. Falconeri*, *Lowii*, *heterocarpum*, and variety *philippinense*, and many others.

The next house is devoted to *Cattleyas* and other Orchids, which Mr. Edwards considers do well together. The house is about 40 feet long, has centre and side stages. Here dwell what are considered the gems: it is enough to mention a few—the grand old *C. labiata*, autumn-flowering variety, represented by six or seven plants; as many of *C. exoniensis*—Mr. Dorn's lovely hybrid. I should mention that among these is a variety I have never seen anywhere else; sepals and petals almost pure white, the lip long and deep crimson-purple, with all the other *exoniensis* properties. Near these stood the *C. Reineckiana*, which proved itself by its flowers last year to be a fine variety; *C. Wagneri*, *Lælia Jongheana*, with three spikes, the strongest plant I have seen of this; *C. Dawsonii*, the rare variety of *C. Mossie*; name *Mariane*, with its white sepals and petals; *C. virginialis*, and the very rare *C. Alexandrae*. On the warmest side of the centre stage stand plants of *Lælia elegans* type, *alba Biantii*, *Turneri*, and *Wolstenholmei*. In a warm corner were located plants of *C. Trianae*; these are now a fine sight. Among named ones in flower I saw varieties *Hilli marmorata*, very lovely; *Atalanta*, *niva*, *Vesta*, *gandii*, *splendens*, besides many other splendid forms from a noted importation. The rare

and lovely *Trichopilia lepida*, *T. crisa marginata*, *T. suavis*, all were close to the glass, hanging over the paths. I must not omit the C. Warneri family, one variety of which I understand the Messrs. Veitch described as the finest they had seen of this lovely Orchid. The *Vandas* are strong and healthy, and do well here, *V. suavis* now carrying several spikes, *V. lamellata boxalli*, *V. tricolor*, &c.; *V. teres Andersoni*, which last summer carried several spikes. Mr. Edwards does not consider this hard to flower if managed properly. I was perhaps most struck by the rude health of the *O. vexillariums*—such leaves and growths. The fine plant of *O. vexillarium giganteum* is making growth this year even larger than that of last year, when it threw a spike of nine flowers, each flower measuring 4½ inches across. Two fine large plants of *C. gigas* were enjoying all the sun they could get.

Among the many plants of that most useful winter Orchid, *Lælia anceps*, I noticed several very superior varieties, one truly a *subperismissima*, and *grandiflora*, with the other varieties, *alba rosea*, *Dawsoni*, *Barkeri*. A grand plant of *L. purpurata*, the variety with pure white segments with over thirty bulbs and several fine leads, promised well to make as fine a display as it did last year at the Devon and Exeter Horticultural Show. Near it, in rude health, with over twenty blooms, I noticed the rare *C. amethystoglossa*; the *C. Mendelli* class are well represented by two or three of the pure white variety, with long deep coloured lip, and several others. The quantities of *C. Mossie*, which have an entire side stage to themselves, again promise a grand sight this year. On this same stage last year over 230 blooms of *C. Mossie* were open at one time. A photograph of this grand sight I was shown. Many in this batch have not yet flowered; all inferior forms have been weeded out, as in the case of *O. crispum*. *7. B.*

CROCUS VERNUS.

A VERY agreeable study of some of the least known forms of the spring Crocus is just now being afforded on the rockwork at Chiswick. The various varieties have bloomed very finely this season, owing probably to the mild open weather and the absence of frost and withering cold winds. For novelty and distinctness of colour and charming appearance there is nothing to compare with a self-coloured variety named *L'Unique*, which is of a pretty rosy-lilac colour, lively in tint, and of much individuality of character. It may be said to stand alone among the self-coloured flowers, and it can be particularly recommended for pot culture. The flowers are not so large as some, but they are of good size and shape, and, as *Crocuses* go, appear to flower very freely. Among other blue or purple varieties *Baron Brunow*, rosy-purple, very fine, distinct and good; *Grand Lilas*, bright lilac-purple; and *Sir John Franklin*, deep violet, are all good. Of white flowers *Blanchard*, *Mont Blanc*, *Queen Victoria*, and *Snowflake* were very good. As a matter of course, there is an inevitable amount of sameness in the white varieties, but they differ in size, shape, purity of colour, and prominence or otherwise of the stamens. The striped flowers now represent a large section, including those that are very dark to those that are almost white. *La Majestueuse*, *Mdlle. Mena*, *Lord Fielding*, *Brunette*, *stripes* and *flakes of magenta-purple*, very fine and distinct; and *Lady Stanhope*, are particularly noticeable for their large, bold, and handsomely-marked flowers. How many reputed varieties of *Crocus vernus* there are may be inferred from the fact that one of the foremost of the Haarlem bulb catalogues numbers forty-four blue varieties, one violet, twenty-eight white, and thirty-one striped and variegated—114 in all, and these lists do not include names found in some Dutch and English catalogues. It was once remarked, but many years ago, that one good blue, one white, and one striped, would do for all in their several sections. This was not seriously intended in all probability, and less so now than in times more remote. Additions are constantly being made by seedlings and also by sports, and the increase goes on year by year. The *Crocus vernus* represents an extremely interesting class of flowers, and we should be glad to see Mr. Barron take in hand a representative collection for the purpose of showing what advance has been made during the past quarter of a century. A word or two

is necessary in reference to Mr. Barron's method of carpeting the ground in which the *Crocuses* are growing at Chiswick. This is done with dwarf *Saxifrages*, and the *Crocuses* send up their flowers through these tufts, and by-and-by flowers and foliage both decay, leaving the *Saxifrages* to enliven the spot, which they do for the remainder of the year.

The Rosery.

ROSES UP CHIMNEYS AND TREES.—Some years since attention was directed to the prodigious waste of running rosettes on bare chimneys and bald roofs and fences; and an earnest appeal was made that these should be draped with verdure and clothed with beauty. Since then a good deal has been done in these directions; still, a great deal more has been left undone. Turn where we may, walls, fences, roofs, chimneys, all seem bald and bare. Cottages, outbuildings, sheds, warehouses, might be greatly improved, and the bald outlines of much hideous architecture hidden, were *Roses* and other plants and trees more generally planted against our buildings. Chimneys also offer special advantages to tender plants, such as *Roses*. Most of them are storehouses of warmth, and many scarce tender *Roses*, such as *Maréchal Niel*, *Climbing Devoniansis*, &c., that might languish on bleak roofs and bare walls, would grow luxuriantly and flower profusely on the genial surface of a chimney. And then the flowering drapery of the *Rose* would not only redeem the chimney from stiffness and ugliness, but convert it into a thing of beauty, if not a joy for ever. And if *Roses* could thus transform chimneys into beautiful objects, what could they not do by way of artistic embellishment to the trunks of trees? It is only needful to look at trees in woods or hedgerows clothed with *Ivy* or *Traveller's Joy*, to see what climbing or trailing plants can accomplish in this way. And *Roses* can do so much or more than these; for, in addition to their foliage, they provide flowers of the most varied colours, and odours of the sweetest fragrance. The latter is most valuable quality in woods. For after the first blush of spring has passed away with its fresh odours of *Violets* and *Primroses*, woods are apt to become dark and damp, and to lack sweetness. *Beech*, *Limes*, *Lilies of the Valley*, may prolong the sweetness of woods, but long before the autumn tints lighten them with the hectic flush of coming tints the perfume has departed. But wreath the trees round with the sweet *Eglantine*, *Roses*, and wild *Honeysuckle*, and the woods remain fragrant till leaf-fall. Not would *Roses* up trees bring fragrance only, but wild and tangled luxuriance and highest beauty. Who that has seen the common *Sweet Briar* or the *Dog Rose* in its simple elegance and wild tangled masses, up or among trees, can ever forget the sight? Such plants are like glowing fountains of beauty. The more petals that fall the more buds seem to open, and there appears to be neither measure nor end to their rich prodigality of sweetness and beauty. *Briers* and *Roses* up the trees of our home woods and plantations would so greatly enrich them as to lend a new charm to the landscape. The verdure of our woods is so deep and dark at times, as to greatly need enlivening with lighter graces and more brilliant colours. It is this that renders *Rhododendrons* so valuable as base lines; rich and beautiful in themselves, the contrast they impart deepens the verdure of the masses of woods and plantations. But *Roses* being less formal are far more effective. They impart the much needed colour without either the formality or the stiffness incident to most sub-plants. *Roses* also climb to every possible variety of height, and droop down from infinitely varied elevations. Their erratic heights and distances, the varying bulk of their masses of branchlets, their varying colours and odours, render them invaluable in woods and plantations.

Apart from the value of *Roses* and *Briers* to run up or climb or roam wild over or among trees, many of them are capable of making respectable underwood or valuable cover. Where *Roses* are too scarce or valuable for such purposes *Sweet* and other *Briers* form no bad

substitute for them. For if it be true—and it is—that beauty unadorned is adorned the most, it is equally or more so that the wilding *Roses* or *Briers* are often by far the more beautiful in woods and plantations; and besides, a good stock of the several varieties of *Dog Rose* and *Sweet Briers* may be sown or planted with the wood. It is easy to cut these out if not wanted, and there is no means of establishing *Roses* in woods equal to working them plentifully on to the arms and branches of wilding *Briers*; plants or cuttings of some of the more common and free growing *Roses* should also be planted in woods, and shrubberies. Some of these may be encouraged to run up trees, and others permitted to ramble into wild masses. There is little fear in having too many of these, and it is easy to reduce them, but most difficult to establish or make *Roses* grow freely on old-established wood unless one has the vigorous roots of *Briers* or the plants already well established to work upon. In all cases where it is needful to establish *Roses* in old woods blocks of roots and soil should be taken clean out, and some impenetrable barrier established between the new soil and the old, as otherwise the tree roots will speedily impoverish the soil provided for the *Roses*, and but little progress will be made in draping the forest trees with higher beauty. The following are among the most suitable varieties for this purpose:—*Gloire de Dijon*, *Maréchal Niel*, *Climbing Devoniansis*, *Cheshunt Hybrid*, *Madame Gerard*, *Belle Lyonnaise*, *Climbing Aimée Vibert*, *Lamarque*, *Celine Forestier*, *Reve d'Or*, *Coupe d'Hebe*, *Paul Verdier*, *Fulgens*, *Charles Lawson*, *Blairii No. 2*, *Chénédiol*, *Madame Plantier*, *Climbing Victor Verdier*, *Général Jacqueminot*, *Anna Alexiev*, *Duke of Edinburgh*, *Maréchal Vaillant*, *Monsieur Boncenne*, *Souvenir de la Reine d'Angleterre*, *Glory of Waltham*, and also the so-called climbing hybrid perpetuals.

The more distinctly climbing *Roses* of the *Arlyshire*, *Boursault*, *Evergreen* and hybrid *China* varieties, such as *Dundee Rambler*, *Queen of the Belgians*, *Splendens*, *Elegans*, *Gracilis*, *Félicité Perpetuelle*, *Princess Louise*, *Rampant*, *Russelliana*, *Queen of the Prairie*, *Selina*, *The Garland*, &c., would all answer well. In mild sheltered positions even the *Banksian* *Roses* might do well up trees, especially the common yellow variety, which is more hardy than the larger flowered richer yellow *Jaune Serin* or the common white and the larger white *Fortunei*. But any free-growing robust *Roses* will look well up trees, though perhaps those of the most slender growths and with the smallest flowers are the more effective, combining as they do the maximum at once of grace and beauty. *D. T. F.*

THE ROSE-HOUSE AT MILTON PARK, as described at p. 267, is a lean-to with a pit in the centre and a path and staging all round. It is built against an ordinary garden wall about 14 feet in height; aspect south-east. Part of the stock is planted out and part grown in pots. Treatment: encourage liberal growth by repotting or top-dressing after flowering, plunge in bed of ashes in full blaze of the sun during summer, and water regularly; syringe every evening to keep clean and healthy; pinch off all buds as they appear, and in autumn take out of ashes and stand on hard bottom in full sun, giving less water in order to get wood well ripened and let plants go to rest. Take indoors about the end of September and encourage to make fresh growth, which will flower from November to March. Those planted out are treated in a similar manner, and come in for succession, being later kinds such as *Maréchal Niel*, *Gloire de Dijon*, &c. The sashes should be movable so that they can be taken off in summer to let the plants go to rest after making growth. I do not recommend a lean-to Rose-house where one has to be built, but an "unequal span," or a "span-roofed structure with a pit in the centre," and "movable sashes," for reasons stated. Best winter-flowering kinds are *Niphetos*, *Safano*, *Madame Falon*, *Isabella Sprunt*, *Souvenir d'un Ami*, *Sombreuil*, *Madame Ducher*, *Abriest Montplaisir*, *Belle Lyonnaise*, *Madame Trifle*, and *Devoniansis*. *Reporior*.

NEW ROSE "THE EARL OF SHEPPOKE."—On Saturday last Mr. H. Bennett, of Shepperton, kindly sent me a bloom of his new *Rose*, named as above. The colour is intense, clear, deep crimson, and, judging from the specimen sent, which was said to have been cut from a small plant in a 4-inch pot, I should say it is a *Rose* of great promise; and it is certainly not open to the objection of being scentless, as it possesses the most exquisite perfume. *T. Clialli*.

The Herbaceous Border.

GEUM COCCINEUM AND HYBRIDS.—We have lately had many lists of precocious children in the garden coming into flower a fortnight or a month before their right time, but I have seen no mention of *Geum coccineum*, many plants of which are full of forward buds, and some are already in flower in my garden. I refer to the semi-double variety, which has now almost superseded the old single form, though that has merits of its own. But the new favourite has a longer flowering period, the flowers last longer when cut, and the colour is deeper and richer. Being only semi-double it produces seed freely, and is very easily raised; so that it is desirable to keep a young stock constantly on hand, though the plants last for several years. By a judicious succession of plants of different ages they may be had in flower every year from April till November; but during the past winter the plants have never been quite without flowers. I generally make two sowings, one in February and another in April. The first sown come into flower in August, when the old plants are going out of flower. The second sowing are set with buds by winter, and if the winter is severe the buds are killed back, and the plants flower with the old ones in May and June; but if the winter is mild, like the last, they come in with the earliest spring flowers. Last spring I bought two hybrids, probably between *Geum coccineum* and *Geum montanum*—both have single orange-coloured flowers, and one I bought from Mr. Robert Parker, of Tooting, under the name of *G. miniatum*. It was a strong plant, such as Mr. Parker always sends to his customers, and in the summer I divided it into twelve pieces, each of which is now a strong plant. The other, which has a strong family likeness to it, was raised and brought out by Mr. Clibran, of Altrincham. This, too, is a very strong grower, and increases very rapidly. They are distinct and new in colour, and seem better adapted to light soils than to heavy strong soils, in which they have a tendency to grow coarse. *C. Woolly Dod, Edge Hall, Malpas, March 5.*

SANIFRAGA STRACHEVIL.—This is perhaps the finest of the cordata section of Saxifages. A fine plant is now in flower in the hardy herbaceous house of James Dickson & Sons, Newton Nursery, Chester. In the same house we saw the rare *Trinanda floribunda* in the flower. It is well named, being one mass of flower, and very attractive from the remarkable brilliant yellow colour of the flowers. No collection of *Trinandas* should be without it. *Edor.*

ANEMONES.—The mild weather we have had has caused these into flower, and most valuable have they been for cutting, especially the bright scarlet variety, *A. fulgens*, which, associated with either the Christmas Rose or *Eucharis amazonica*, produces a most striking effect. Seeing the great use to which *Anemone fulgens* may be put, and the early season at which it comes into bloom, it should be largely planted in sheltered sunny spots under walls, or on warm borders where, if necessary, the plants could be protected by having hand-lights placed over them. I once tried them in pots for forcing, but found them impatient of artificial heat, and now I mean to plant along the fronts of some of the houses, close up to the bricks. There I think they will feel just sufficient warmth below to help them into blossom, and if so, a row of them will afford something to cut at. I find the best way of getting the other tuberous-rooted kinds is to sow seed in beds, where they come up thickly, and yield masses of blossoms. If sown at once they will flower freely in the autumn, and the same again early in spring. *Anemones* like rich loose soil in which there is plenty of sand to keep it open and porous; so favoured the roots be sung, and keep from wet, to which they are subject in ground that remains wet and cold. *J. S.*

SANIFRAGA PURSERIANA.—Let the praises of this little gem be sung ever so often, yet it will richly deserve everything recorded in its favour. Mr. Barron has it now at Chiswick in pots in a cold frame, and also on the well-finished rockwork, and in both cases it is most charming. Under glass the flowers are larger and purer in colour than on the rockwork, and look like so many floral bowls raised upright on their tiny stems. On the rockwork it is also exceed-

ingly pretty, and very free; while it is all the more valuable because blooming so early. It requires to be let alone till it becomes nicely established on tufts, and it should have a somewhat elevated position on the rockwork. There is a great number of these dwarf Saxifages, and the one under notice is a chief gem among them.

FORESTRY.

FORESTRY divides itself into two branches: the first is called silviculture, or the culture of woodlands in all that concerns the crop which grows upon them; the second refers to their administration from an economic point of view, or in regard to the supply of timber for sale or use by the community, and the revenue to be derived from them.

As regards the first, it may be said that there is no mystery in scientific forestry. It means simply to observe the action of Nature in a forest, and to follow it, or to utilise it for our advantage when we are able to do so. Its object, then, should be to obtain the utmost possible advantage from the soil, by keeping it always covered with a growing crop of trees; and, when the trees arrive at maturity, to remove them in

calculation will show that a tree 10 feet in girth, which makes a ring of wood of only one-eighth of an inch in thickness, adds to its bulk at the rate of rather more than 1 cubic foot of timber annually for every 10 feet of the length of its stem—or, in other words, such a tree, if its stem be 30 feet in height, will in thirty years have increased in bulk by at least 100 cubic feet of solid timber. At the same time, during these thirty years the young trees which are springing up will become perfectly hardy and capable of supporting the whole force of the summer heat and winter frost. Nothing, then, is lost by the system of natural reproduction, as must be the case when a forest is cut down to be replanted; for not only in the latter case is there a degradation of soil from exposure, but also a dead loss in the production of woody material during the whole time that both the old crop and the young can remain on the ground together with mutual advantage.

But it is not only in the removal of the timber and the reproduction of the forest that we ought to study the action of Nature. It is equally necessary that we should do so in the felling for improving the growing crop, or, as they are commonly called, thinnings. To understand this, let us glance at the constitution of a high timber forest in its natural state, that is to say, a forest, whatever be its age, springing from seed, and therefore capable of living and thriving through a long series of years. In such a forest the

FIG. 48.—VIEW OF WIND MILL AT FARSON DROVE, NEAR WISBECH. (SEE P. 335.)

such a manner that the smallest possible interruption may be caused to the productive work of Nature in the forest.

PRACTICAL MANAGEMENT.

In a natural state, the reproduction of the forest is effected by the germination of the seed which falls from the trees in it, whenever the necessary air, light, and warmth are admitted to the ground, by the fall of any tree, either from accident or age; the work being carried out gradually, and the soil never being exposed over any large area at once. For the young seedlings which spring up would wither and perish at once, unless they were sufficiently shaded. So in forest operations, when the time has come for the removal of the timber, on no account should the ground be anywhere cleared of trees at once; but a commencement should be made by felling a tree here and there, and so breaking the thick cover of the forest, to allow sufficient air and light to reach the ground, and so cause the seed which has fallen to germinate. In this way, about one-fifth of the mature trees should be removed every five or six years, never breaking the cover by making large gaps in it, but taking a tree here and there, and always leaving the finest and most vigorous trees till the last; so that in about thirty years the whole of the old trees will be cleared off, and a new forest established in their place. Thus the seeding of the forest will be effected by the agency of the finest trees, which will be themselves all the while increasing in bulk, and thus the productive power of the soil will be utilised to the fullest possible amount. A short cal-

tures will, when young, form an almost impenetrable thicket of various heights; later on they begin to assume a definite form, and being in close contact with each other they soon begin gradually to lose their lower branches, which fall off and wither; but as a compensation they throw all the vigour of their growth into their heads, and as these push themselves upwards, seeking the light of the sun, the stronger ones overtake the weaker, so that a certain number of the latter perish and disappear each year. When about half their full age the trees will have attained their full height; but from that time till they arrive at maturity they go on always augmenting the diameter of their stems, but at the same time decreasing in number; so we may calculate that, if 1600 trees of 4 inches in diameter can stand and thrive on an acre of ground, there will not be above 400 when the trees are 8 inches, 200 when they have attained 12 inches, and from 100 to 140 when they are 16 inches in diameter. In our thinning operations, then, these considerations should be our guide. In the early stages of a forest's growth, there is little to be done except to keep the heads of the young trees of the most valuable species from being overtopped by those which stand near them; and this can be best done, not by removing the others, but by cutting off or breaking their tops, for it is in this stage that the process of natural pruning is going on, which Nature does so much better herself than we can do for her, and to this end it is necessary that the trees should grow as close as possible together. Later on, when the trees have taken a more regular form, we can

assist Nature, and at the same time save much valuable produce by judicious thinning, which should be arranged so as to pass through the whole forest at intervals of from ten to fifteen years, so that the whole area may be operated on in turn. In executing these, the most delicate of all forest operations, it will be well to remember that their object is to give room to the heads of the trees, and not to their stems; for the stems will never be too close together as long as the heads have room properly to develop themselves. The details, however, which govern the operation of thinning differ for almost every species of tree operated on, and to touch on them would be to enter upon a whole course of lectures on forestry. It will be enough to say here that in every case the favouring of the most promising trees and the removal of the weaker ones, together with the preservation of continuous shade to the surface of the ground, while all the trees have sufficient room to grow, should be the objects aimed at.

ECONOMIC MANAGEMENT.

The second point to be considered is the administration of forests from an economic point of view or with reference to the revenue to be derived from them.

The basis on which all sound forest management depends is the revenue which any forest can be made to pay—that is to say, the income which it will

whole of the present crop of trees will be removed, and the youngest now on the ground will have come to maturity. This will be about 200 years for Oaks, 120 to 150 for Beeches and Scotch Firs, and so on. These divisions are again subdivided into (usually) four or five working subdivisions, or compartments, to each of which a sub-period of thirty years or thereabouts is assigned, as being sufficient for the removal of all the old trees in it, and the reproduction of the new crop. There must be, then, as many sub-periods in the number of years assigned for the complete working out of the forest as there are sub-divisions in the whole forest. We take whichever of these subdivisions contains the greatest number of mature trees, and assign to it the first sub-period of thirty years, calling it No. 1. We count and measure the trees in it (neglecting all, if there be any, of less than a inches in diameter), and ascertain the total volume of timber they contain. This, divided by thirty, or whatever is the number of years in the sub-period, will give, as is evident, an amount or volume of timber somewhat short of the possible annual yield, but near enough to it for all practical purposes: it remains, then, only to remove each year from this compartment the quota of timber indicated above, following, in doing so, the method for the reproduction of forests explained just above—that is, we should remove one-fifth of the trees from one-sixth of the surface of the subdivision each year, or thereabouts,

But besides forests which spring from seed, there are others which consist of shoots springing from the stools or stumps of trees which have been killed, and which are commonly called coppiced forests. In many cases these give very good returns for hop-poles, mine-stays, bark, and other purposes for which large timber is not wanted. Their management is well understood, and the only points on which suggestions may be offered, are—

1. The necessity of giving sufficiently long intervals between each felling, as every time the copse is cut the soil suffers from exposure, and its fertilising power is wasted, as it is also by the production, during the first four or five years after the cutting, of a mass of useless grass and leaves, which profit nothing.

2. The necessity of using sharp instruments for felling and cutting the wood close to the ground, leaving the stools or stumps of such a form that the wet may run off them. These precautions are necessary for ensuring healthy re-shoots.

3. The cutting of the copse, if possible, in the early spring instead of in the winter, as is usually the case. If the work is done just before the sap begins to move the shoots are made at once, before wet and rot have attacked the stools, and rendered the production of healthy vigorous shoots impossible.

It may be added that the more standard trees that are reserved in a coppiced forest the greater will be its value; and there is nothing to prevent their flourishing over the lower growth, which serves to keep up their heads, and to give them a clean stem.

Now what is the practical application of all this? We have in Scotland about 800,000 acres of forest which have been planted during the last 100 years, for few of them exceed that age. Besides these, there is a small remnant of the old natural forests in Strathspey. In England we have, belonging to the Crown, about 50,000 acres of forest, the greater portion of which has been planted within the last hundred years also, with some remnants of the old natural forest, chiefly in the New Forest. It is impossible to speak too highly of the admirable work done by the able men who have created these forests at Scone, Blair Athole, Dunkeld, in Strathspey, on the Findhorn, and at Beaulieu, Scotland, as well as in some of the English Crown forests. In our colonies, including India, there are millions and millions of acres of forest land, some of which is of the greatest value, so that Great Britain is perhaps the country most richly endowed in forest wealth of all the countries of the earth. Every one, not only in our own country but elsewhere, is interested that all this great forest-wealth should not be wasted or frittered away by a single generation of men. But nevertheless, what is the future of all the forests? I have visited many of them, and scarcely anywhere did I see any of that young growth which is the link uniting the forest now on the ground with that of the future. Can any one say, then, that the future of these forests is assured? As they exist at present one of two conditions must befall them—either they will be cut down any day by timber dealers, or they will in due course perish naturally and disappear of themselves. In either case the result is deeply to be deplored, for when once the forest disappears it can only be replaced at a great expense of time and money. *Extracted from Col. Pearson's Lecture before the Society of Arts.*

FIG. 49.—WOOD MILL: SHOWING CONSTRUCTION OF THE WALLS. (SEE P. 339.)

produce in proportion to the volume of the standing trees; or, in other words, its capitalised value. To this end a forest should be considered as so much capital, represented by so many cubic feet of wood, while the amount of wood produced each year by its growth represents the interest thereon, and, in fact, is the revenue of the forest. It is evident that it is possible to cut and remove every year a quantity of timber equal to this annual increase of wood without diminishing the volume of the standing crop. The quantity that can be so removed is the proper yield of the forest—that is to say, the continuous yield; and French foresters have called it "the possibility" or possible annual yield—of the forest.

Now, if we suppose that a period of 150 years will be required for the youngest trees in a forest to arrive at maturity, it is evident that the 150th portion of it might be felled every year, and that the increase of timber in the first year would equal the volume taken away. But, as we cannot apply such a plan in practice, and at the same time insure the reproduction of a high timber forest, we arrive at the possible annual yield in another way.

It is in order that we may have to deal only with areas of a workable size, the forest is divided, in the first place, into large blocks or divisions, which should not be more than 2500 or 3000 acres each, and arranged generally so as to be convenient for the roads, rivers, or other means of transport for the timber. Each of these must be considered, and dealt with as a separate forest by itself; and to each a period is assigned, in which the

taking care not to exceed the volume indicated as the possible annual crop.

The other subdivisions or counterparts will be numbered 2, 3, 4, &c., and to each of them a sub-period will be assigned in succession. In the meanwhile, the necessary thinning, and the removal of trees that would otherwise perish, must be carried on continually during the first sub-period in all the other subdivisions, so as to go over the whole ground at regular intervals, not exceeding fifteen years each. At the conclusion of the first period No. 1 will contain a young crop of trees, from one to thirty years old; and then No. 2 will be taken in hand; and after No. 2 then No. 3, and so on, until in the full period the whole forest will have been renewed without the ground having been once entirely cleared of trees. Any one visiting Baden Baden will do well to explore the forests in the beautiful valleys of the Oos and the Murg in its immediate neighbourhood, which furnish a splendid example of the successful working of forests on this system. As examples of private forests which have been admirably managed in the same way, I may mention those of Prince Furstenberg, near Rippoldsau, to the east of Baden Baden, where there are some excellently constructed and most ingenious devices for bringing timber down the mountain torrents to points from which it may be carted away.

* Trees cannot be made to grow spontaneously in a forest, as we can place the men on the squares of a chess-board. The distribution of the felling, must therefore rely upon numerous cultural exercises which develop themselves from time to time, which time will not admit our noticing here.

WOOD MANUFACTURE AT WISBECH.

In the *Gardener's Chronicle* for June 18 last, p. 787, an interesting description was given of the manufacture of wood from the leaves of *Isatis tinctoria* as still carried on in the neighbourhood of Wisbech—a curious survival from the times when, as Cæsar tells us, the Britons stained themselves blue with woad. Prof. Oliver has succeeded in obtaining sketches both of the exterior and interior of these rude mills, and I am indebted to him for the loan of the illustrative sketches. Fig. 48 is a general view of the building. Upon referring to the article before mentioned it will be found that the central building is described as being circular with a conical thatched roof. Fig. 49 represents a portion of the mill, the walls of which are described as being built with turf, about 3 feet wide at the base and narrowing upwards. The blocks of turf are about a foot deep, cut in a slanting direction and arranged in a herring-bone fashion resembling old Saxon brick-work.

Fig. 50, p. 339, represents the grinding machine, which is contained in the circular building before alluded to. This machine is worked by direct shafting, one being attached to each of the grinding wheels, which, as will be seen, are somewhat conical in shape. They are 7 feet high on the outer side, and 6 feet 6 inches on the inner. The cross bars are of iron, and the wood leaves being thrown into the mill, and these drums or wheels passing over, are soon reduced to a pulp. *John K. Wilson, Acct.*

Orchid Notes and gleanings.

WORK IN THE HOUSES.—In the East Indian-house the winter-blooming species of *Saccolabium*, such as *S. giganteum*, *S. Harrisonianum*, and *S. violaceum*, should be cleaned, and have all the old material removed from about their roots, re-surfacing them over with freshly-gathered sphagnum moss. We prefer growing these soft-rooted species in baskets or cylinders, as in this way they are better aerated, and the roots are in a better condition for taking up supplies of nourishment from the atmosphere than when they are confined to pots. The early-flowering variety of *Angraecum sesquipedale*, which will now have passed the flowering stage, should be treated in the same way as advised for the *Saccolabium*, except that this, being a harder-rooted plant than the *Saccolabium*, it will be found to do and retain its roots in a healthy state as long in a pot as in a basket. The late-flowering form of this plant, which is much the finer of the two, will now be showing its spikes freely if the plants are healthy and strong. They are shy-rooting plants, and require to be very carefully handled when they need repotting. *Vanda gigantea* will now be passing out of flower, and should be sponged over and put right at the roots for the season. Any small plants of *Aerides* and *Vandas* that a shift would benefit ought to have that attention, so as to get them re-established before the sun obtains much power. Most of these will grow well in pots, giving them abundance of drainage, and crocking them up over the roots nearly to the surface of the pots, finishing off with a couple of inches of sphagnum moss. Where a careful hand guides the water-pot, 3 or 4 inches of sphagnum moss may with advantage be placed over the roots of these young plants, but it should be rammed in firmly so as not to hold too much moisture, and a sprinkling of sand through the moss will assist in preserving the roots. Some of the *Aerides* do better in baskets than in pots, especially the shy-rooting species, such as *A. Veitchii*, and *A. roseum*; and even when in baskets these species should not be overloaded with sphagnum about their roots, as when this is the case and the plants are not carefully watered a spotty and diseased condition in the plant is soon induced. A light fumigation once a fortnight or so through the spring months will do much towards keeping the plants in this house clear of the yellow thrips for the season. Good shag tobacco should be used for fumigating these plants, as a light dose of this will be more effectual than a strong dose of the best tobacco-paper. Plants of *Odontoglossum Phallopis* that have finished flowering may be divided and repotted, giving ample drainage, and using the best fibrous peat with a little sphagnum moss about their roots. We find when this plant is grown on large enough to occupy a 24-sized pot that many of the old bulbs commence to get decayed, and if this is not arrested the whole plant soon gets affected. When the plants get into this state we split them up into pieces large enough to fill 18-sized pots, when they soon get established, and grow away freely for several seasons. *J. Roberts, Ginnersey-street.*

PHALLOPIS SCHILLERIANA.—In March, 1881, I saw three plants in bloom at Mr. C. Perkins, Kirkley Hall, the original plant with over 160 flowers, and the other two, which had been taken off a flower-spice on the old plant some years previously with over 80 and 120 flowers each. I have lately seen these plants again in flower, but all with an increased number. The original plant had thrown up a rooted growth from last year's spike, which Mr. Perkins kindly allowed me to cut out and take home, and this plant, not twelve months old, then carried no less than fifty-eight fully-developed flowers. The variety is much more than usually sweet-scented, of good colour and fair form and size. The plants are grown in a mixed stove, where they get more light and less shade than is usually allowed *Phallopis*. These have thick leathery leaves, considerably longer and not so round and broad as is generally the case with home-grown plants; in fact, they strongly resemble the leaves of the strongest imported plants. *Norman C. Cobson, Oakwood, Wylam-on-Tyne.*

TRICHOPILIA SPANIS ALBA.—This rare and beautiful variety is now flowering with Mr. E. S. Williams at Holloway. It is a charming plant, and is very free-

flowering, producing its white blossoms when white flowers are in much request. In habit of growth it resembles the type, and the fine bold dark green leaves make a striking contrast to the delicate flowers. It succeeds well in the cool-house, and requires treatment similar to other cool Orchids.

MR. BULL'S COLLECTION.—In Mr. Bull's nursery the *Odontoglossum*-house still contains some fine examples of this genus. *O. crispum roseum* is a lovely variety with well formed flowers; and amongst some good forms of *O. triumphans* there is a remarkable specimen with two spikes—one has twenty-five flowers and the other twelve. In the Cattleya-house *C. Trianae* is flowering very profusely, some of the varieties being remarkable for the rich colour of the lip. One has been named *C. Trianae magnifica*. It is of fine form, the sepals and petals delicate rose, the petals having a spot or blotch of crimson on the tips—a distinctive mark not at all common.

PHALLOPIS TETRASPIS.—This rare, very distinct, and beautiful species, is now in flower at Messrs. Veitch's, Chelsea. The habit and characteristics of the plant are those of *P. Ludemanniana*; the flowers are rather larger than those of the latter species, and are pure white, except the crest of the lip, which is yellow.

THE BLENDON HALL COLLECTION.—Blendon Hall is the residence of W. C. Pickersgill, Esq., at Duxley, who has a comparatively small collection of Orchids, but which are excellent in quality, many of the varieties indeed being magnificent. At the present time there is a grand display of *Lycaste Skinneri*, forming quite a show in themselves, two of the varieties being exceptionally good—the finest I have ever seen. One named *gigantea superba* measured 6½ inches across the outer segments and 2½ inches in breadth, the colour a beautiful bluish-white; the petals are very broad, and suffused with rosy-purple; labellum white, with light rosy-purple markings in the centre. This flower, as its name implies, is gigantic. The variety *virginalis* is a great beauty—I think the gem of the collection; the outer segments are pure white, sparkling as if studded with diamonds, upwards of 6 inches across and 2 inches in breadth; petals white, slightly suffused with pink at the base; labellum delicate rose with white margin. *Formosa* is a light variety, and very handsome in contrast with the highly-coloured *rubella*. But the most remarkable plant in this collection is *Dendrobium heterocarpum*, probably the finest specimen in this country, having upwards of thirty gigantic pseudobulbs, and showing eight young growths. The largest pseudobulbs are upwards of 2 feet in height; and six of them are at the present time laden with fragrant blossoms; the variety leaves nothing to be desired, being simply superb. There is also a chastely beautiful large variety of *Cymbidium chloranthum* in flower. The collection includes besides some grand specimens showing in bloom, the most noticeable being *Cattleya labiata* Warneri, with about thirty pseudobulbs and four flower-sheaths—a magnificent variety, producing enormous flowers; *Saccolabium retusum*, a grand plant, showing two flower-spikes; *Dendrobium Farmeri*, a handsome healthy specimen, showing fourteen flower-spikes; *D. thyrsoiflorum*, with splendid growths; and some very healthy *Vandas*. A grand plant of *Aerides Lobbia* has fourteen pairs of leaves—a really handsome plant. Of *Cattleya gigas imperialis* there is a fine specimen with thirty pseudobulbs. This is one of the very finest forms of this splendid species. There is a remarkably fine specimen of the long-bulbed variety of *Cattleya coniensis*, with between twenty and thirty large pseudobulbs. *Cypripedium caudatum* is also well represented, this specimen producing annually from fifteen to twenty flowers. *Dendrobium superbiens* is evidently quite at home, making grand progress. Of *Miltonia Moreliana atrovirens* there is also a large pan, in the best of health; also *Laelia anceps* alba and many other fine things. Nearly all the Orchids in this collection have been grown from small plants in an ordinary span-roofed plant-stove, where *Trichoceras*, *Matanzas*, *Crotans*, *Ferns*, *Gardenias*, and a general collection of stove plants are cultivated, and the condition of the plants abundantly proves that they are quite at home. That they are handled in a practical and masterly manner is very evident, and a word of praise is due to Mr. F. Moore, whose management of this place for upwards of ten years has, it is needless to say, given his employer every satisfaction. *Leo Gordon.* We have had an opportunity of seeing flowers of the *Lycastes* and of the *Cymbidium*, which bear out our correspondent's statements. [Ed.]

The Flowery Garden.

LILIU ABRATUM, &c.—These grand additions to the herbaceous flower borders should now be planted, and if the operation can be carried on simultaneously with the digging of the borders so much the better. A light, rich, and deep soil, with thorough drainage, appears to suit them best. The best situation is at the back of the borders, with a sheltering background of shrubs and a southern aspect. We usually take out the soil to the depth of 6 inches, on which is placed an inch of silver-sand, and on this the bulbs, either three, five, or seven, according to the size of the patch required; but, as a rule, five will make a very fine display. These are covered with another inch of sand, and the soil levelled, the site being marked with a stout caken peg a foot or so long. They will amply repay for any amount of trouble bestowed upon them. They are also very suitable for planting in patches amongst *Rhododendrons*. The shelter afforded by these appears to suit them well, and they thrust up and expand their flowers over the tops of the *Rhododendrons* at a time when the flowering season of the latter is quite over. Many of the hardier sorts, such as *L. candidum*, *L. aurantium*, and *L. tigrinum*, are also very suitable for the above purposes, as is also the Yellow Turk's Cap Lily. These must all be carefully marked, and only disturbed at long intervals when the roots become very much crowded. *Gladiolus brechenleyensis* in particular, and many other sorts in general are great additions to the herbaceous border, and should be planted at once about 5 inches deep, and be well embedded in sand; there is no more useful and showy plant than *G. brechenleyensis* for the purpose, and it is so accommodating that many little sheltered nooks may be found where they can thrust up their spikes and interfere with nothing else.

HARDY ANNUALS.—A first sowing of the early flowering and most showy sorts should be made at once in small and under glass for filling up vacancies in the herbaceous borders; such fine showy things as Prince's Feather and Love-lies-Bleeding, however, may be sown at once in the open border in patches where they are intended to flower—from 6 to 8 feet from the margin of beds is best, and they will pay for a deep and rich soil. A very showy bed of *Antirrhinum* may be obtained by sowing the seed at once where the plants are intended to flower, so also will *Erysimum Perofskianum* make a good orange-coloured bed in the autumn if sown at once in good ground and well thinned afterwards.

TENDER ANNUALS.—It is as well to bear in mind that the sowing of the various sorts of tender annuals must soon take place, so that attention must be directed to the accumulation and preparation of fermenting material for securing a gentle bottom-heat for the purpose, and as at this season such materials are in great request in every department, it will be fortunate for those who have been able to secure a good supply of tree leaves, as a small quantity of fermenting dung mixed with these forms a far better and sweeter medium for obtaining the required temperature than all manure, which is apt to be too violent.

ROCKERY.—Several things here are now in flower, or growing fast and showing for flower, so that a neat appearance becomes imperative, and the necessary reduction in size of the strong growers may be commenced at once. Sedums, the moss *Saxifrage* and scarlet *Monarda* are very apt to outgrow their bounds, and must be kept under, the great object being to get as great a variety as possible in the space. The ground should be thoroughly well cleared of all extraneous matter, then well top-dressed with some rich new compost, which should be simply raked in as the operation of regulating the plants proceeds; it is not yet safe to fill up vacancies from the stores in cold pits.

PLEASURE-GROUNDS.—It is astonishing to see the rate at which the grass has been growing through the winter, and it is worthy of note that, commencing on January 25, we went over a considerable portion of the lawns with the mowing-machine, and edged the

flower-beds, giving them quite a summer-like appearance; and we find that, according to present appearances, this practice must be followed up, and that we may expect that the season for the general routine of pleasure-ground work will be much earlier than usual, so that if any improvements or alterations are in progress, no time must be lost in bringing them to a close at once, and all operations connected with the digging and renovating of empty beds, or beds with flowering shrubs, &c., must be completed, so that nothing may interfere with the requisite finished appearance of the dressed grounds. *John Cox, Keble, leaf.*

Grapes and Vineries.

The earliest house can still be kept at a night temperature of 65° with a rise of 10° by day. Raise the temperature to day heat early in the morning, so that the forcing is done when there is the greatest amount of sun and light; on cold sunless days a few degrees lower will be better than excessive fire-heat. Admit air early in the day on the back ventilators, and increase it as the temperature rises, being careful to avoid cold draughts. On bright days close the house early enough for the temperature to reach 85° after closing, and thoroughly damp down paths and borders. Water the border when dry with tepid manure-water, giving sufficient to go thoroughly through the border, for if not done well the Vines will suffer for want of moisture; keep the evaporating pans filled with manure-water, as the ammonia will greatly assist the Vines, and keep respicer down. Add fresh fermenting materials to outside borders as the heat declines. Succession Hamburghs will now be ready for thinning, and if not already done take off all surplus bunches at the first opportunity, for if left on longer they only weaken the Vines and rob the other bunches. After thinning is completed give the border a thorough watering with tepid manure-water, and keep the temperature as advised in previous Calendars. Hamburghs started about February 1 can be kept at a night temperature of 60°, with a rise of 10° by day. Muscats in bloom keep at a night temperature of 70°, and if the nights are very cold a few degrees lower, with a rise of 10° by day. Damp the paths and borders with tepid water early in the day, so that it will dry up before noon; and then damp the house again at closing time on bright days, but if cold and sunless do not damp the house in the afternoon. Tap the rods twice daily to disperse the pollen, and if they do not set freely fertilise them with Hamburgh pollen, but where the Vines are in a good state tapping the rods will be sufficient for them to set well. Let the evaporating pans go dry until they are out of bloom, and admit air on the back ventilators early in the day. Do not stop the growths during the period they are setting, but take off the surplus bunches as soon as possible. I usually take a good many of the bunches off before they come into bloom, and the remainder never fail to set well. If not already done start the latest house of Muscats at once, at a night temperature of 50°, with a rise of 10° by day, letting it run up to 75° at closing time on bright days, to save fire-heat. Keep the evaporating pans filled with clear water, and syringe the rods thoroughly several times daily. All late varieties of Grapes for keeping through the winter should by this time be started, for a little fire-heat now will save a great deal next autumn, and the Grapes will keep much better than if ripened late. All our black Grapes were thoroughly ripe last year by the middle of September, and cut from the Vines on January 7, and they have all kept satisfactorily and will do until April. Keep them at a night temperature of 50°, with a rise of 10° by day. Keep late Hamburghs as cool as possible, leaving the ventilators open night and day. Do not close for a few degrees of frost, but if severe close them. Early pot Vines must have liberal supplies of manure-water, and the paths and borders be damped down several times daily. Keep the night temperature at 45°, with a rise of 10° by day. Grapes still hanging in the fruit-room keep as near 45° as possible, but with the mild weather we have had this winter our Grape-room has sometimes stood at 50° without fire-heat. Do not use fire except to dispel damp if the temperature keeps up to 45°. Fill the bottles with soft-water of the same temperature as required. *Joshua Atkins, Lockinge Gardens, Wantage.*

THE Twelfth Spring Exhibition of the Bristol Chrysanthemum and Spring Show Society will be held in the Victoria Rooms, Clifton, on March 22 and 23.

The Pine Stove.

NEWLY-POTTED plants making their first growth have a tendency to become drawn at this stage, owing to the absence of sunlight; therefore extreme caution is necessary to prevent this by judicious ventilation and by keeping the plants close to the glass. Give a little air on every favourable opportunity; this is best done at mid-day, say from 11 A.M. to 2 P.M., if the temperature does not recede below 70°. This is an important point that should not be lost sight of, for should the plants become drawn now they will never afterwards assume a robust and sturdy habit or acquire the same stamina in after-growth. Those plants that were potted into fruiting pots last September and kept steadily growing all through the winter in a light structure will now require more room. These are a useful lot, which will show their fruits in July and August and ripen them in November and December, after the summer batch is finished. A good method of plunging is to get a number of empty duplicate pots exactly the same size as those containing the plants that are about to be shifted, place the empty pots at measured distances of 2 feet apart each way in the places where the plants are intended to occupy; this distance will be ample for the large varieties, such as Smooth Cayenne and Charlotte Rothschild, &c.; a distance of 22 inches will be sufficient for Queens or the small varieties. When the empty pots are placed in position tread the tan or other plunging materials firmly round the pots: when this is done remove the empty pots one at a time, then place the plants in the holes thus made, putting the largest at the back. Any plants that have drawn to one side should be placed with the leaning side to the north, when the action of the sun and light will draw them back into a vertical position. Examine those plants that have stood in the beds some time; see that the pots are level, to take water, and if the plunging material has shrunk from the sides of the pots make it good. If the beds have sunk generally make them up to their proper level with tan or other material. The young leaves in succession plants and growth made during the dull winter months have a tendency to stick together, in that case they should be assisted to unfold their leaves by carefully disengaging them by the hand or a gentle touch with a stick, and those leaves that touch the glass should likewise be got down with care. Where succession plants are shifted put them into their permanent place so as to avoid unnecessary moving, which only breaks the finest leaves. Where the plants are transferred from one place to another never under any circumstances tie up their leaves, as it is an error to do so. *D. Wilson, Castle Hill, Devon.*

The Hardy Fruit Garden.

FINISH at once the pruning and tying of any fruit trees that from any cause yet remain undone, with the exception of protected Fig trees, from which it would be unsafe to remove the covering material for some time as we may yet experience severe weather. All pruning, training, and staking ought now to be completed; and the freshly bordered borders, with the effectual mulching and labelling of newly planted trees will combine in giving a finished appearance to the winter routine work in this department. Where the Gooseberry bushes are much affected by caterpillars, means should be taken to subdue the plague in every stage of its existence, and if nothing has been done in the way of removal of the surface soil from beneath the affected bushes, that operation may yet be performed with advantage. In the case of established bushes that bear heavy crops a liberal use of rich surface dressing to replace the removed soil will be of great assistance; while the destruction of the chrysalids will be best secured by using the old soil for the purpose of covering up heaps of rubbish being charred. Before the wall trees break into bloom it will be well to carefully scan them over in order to see that no scale has been suffered to escape, and again touch with mineral oil if it be found necessary. American blight on Apple trees should also be carefully looked for in the early part of the season. Use a strong infusion of Quassia, tobacco-water, sulphur, and soft soap applied with force from the garden engine on all fruit walls before the bloom-buds burst; and

where aphides have been very troublesome during the previous season it may be necessary to use the same materials thickened with clay and applied with a brush to all nail-holes and other cavities, if not already done, especially on Cherry walls.

Protecting materials will now soon be required for the most forward blossoms. Prepare for its immediate use should bright sunshine prevail, tempting forward the bloom, by looking over the available stock, repairing it where necessary, seeing to the security of any loops, strings, or rings used, and procure additional appliances where required. The branches of Silver Firs, where obtainable, are means of protecting the bloom from frost that ought not to be despised where more convenient material is wanting. Where stocks have been duly prepared by being headed back, as advised some time ago, grafting may now be proceeded with. Rind grafting may be adopted for the large limbs of cut-back trees with advantage, having ease of execution combined with good results in its favour. For smaller stocks no form is better than the whip graft, which may be depended upon as being one of the best modes of performing the operation. Small stocks are not, however, much worked in private gardens, except to increase some local variety, or when the operator has a hobby for the work; but for the establishment of approved varieties on large healthy trees previously producing inferior sorts, grafting becomes one of the most useful operations of the hardy fruit department. It may not be out of place to remark that old trees which have become unhealthy are rarely rendered more vigorous by being cut over and regrafted, and such trees certainly are not worth the trouble of the attempt. If clay be used for covering the junction in preference to grafting-wax, it ought to be well tempered some time before it is required for use, mixing well with cowdung and moss, or chopped hay. Let all dwarf stocks be worked as low as possible, and after claying let them be earthed-up, to prevent the drying and consequent cracking of the clay. A good covering of moss should be firmly bound over all elevated grafts, which, with occasional sprinklings from the rose of a water-pot in drying weather, will preserve the clay in a sufficiently moist condition. A useful grafting wax can be made from equal parts of resin, tallow, and bees-wax, by simmering over a slow fire, and which will save much of the after attention required to prevent cracking where clay is used. *Ralph Crossling, St. Fagan's.*

FRUIT NOTES.

Apple Cox's Pomona.—This is, in my opinion, one of the very best Kitchen Apples in cultivation. The tree is a great and constant bearer, producing fruit both large and handsome, which keeps in good condition for several months; in fact, it has kept with me better than the Blenheim Orange, which is enough to show its good qualities. I would advise all who have not grown it to give it a trial. It would be a boon to market growers; for, besides being a sure and heavy cropper, its appearance is such that when placed side by side with its rosy-cheeked rivals from across the Atlantic, it seems to put them quite in the shade. *H. L., Syndale Park, Faversham.*

Apple Golden Harvey.—To any one requiring a dessert Apple of the highest quality, in use from December to August, I can recommend the Golden Harvey as being equalled by few, if any, for richness and flavour. To have it in the best possible condition the fruit must be thoroughly ripe, and not removed from the tree till the leaves begin to fall, and are therefore no longer of use in maturing and elaborating the juices so necessary to produce flavour of the richest description. After being gathered the fruits should be laid on boards till dry, and then be packed in air-tight boxes, when they can be taken out as required, and will be found to be quite firm, and to have arrived at the highest point of excellence. *A. L. H.*

SCILLA bifolia.—There are not many early-flowering hardy plants which can vie with this in beauty, and still fewer which surpass it. Perhaps the type, with its lovely blue blossoms, is preferable to either the pure white or the flesh-coloured varieties. The "Starrie Inchin" of the old writers still seems to occupy the same place in the affections of the horticultural world that it did many generations ago.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, Mar. 13	Fadhon of Cambles, &c., at Regent's Park, open to end of week.
TUESDAY, Mar. 14	
WEDNESDAY, Mar. 15	Meeting of Horticultural Society: Meeting of Royal Horticultural Committee, at 11 A.M.: Scientific Committee, at 4 P.M. Exhibition at Town Hall, Manchester.
THURSDAY, Mar. 16	Sale of Imported Orchids, at Stevens' Rooms.
FRIDAY, Mar. 17	Luncheon Society's meeting, at 8 P.M. Sale of Imported Orchids, at Stevens' Rooms.
SATURDAY, Mar. 18	Sale of Hardy Plants and Bulbs, at Stevens' Rooms.

A VERY important paper on the TEACHING OF FORESTRY was read recently at the Society of Arts by Colonel PEARSON, and by courtesy of the Society we are enabled to lay before our readers in another column some lengthened extracts relating to the more practical portions of the subject. Colonel PEARSON began his observations by defining the nature and objects of scientific forestry as follows:

"1. The obtaining, within approximate limits, of a regular sustained revenue from the land which the forest covers; 2. The utilisation, to the fullest extent possible, of the natural productive powers of the soil; 3. Progressive improvement in the value of the property; 4. Final realisation of the crop to the greatest advantage."

In this country the management of woods has hitherto been confined mainly to cultural operations, designed rather with a view to the present advantage of individuals, than to future requirements of the country at large, though of course not wholly so.

We cannot follow Colonel PEARSON in his historic survey of the condition of forests in this and other countries, and of the gradual rise of systematic forestry as now practised in Germany, France, and some parts of India; nor is it necessary here for us to say anything as to the advantage that may accrue from the extension of properly devised schemes of forest management in our colonies, and, indeed, also at home, for they are obvious to any one who has paid the least attention to the subject. The forest management in India has proved very successful, and in a way that commends itself to the revenue officers, who are apt to look coldly enough upon expenditure which is not reproductive. Thanks, however, to such men as Drs. BRANDIS and CLEGGHORN, forest administration is successful even from a commercial point of view. In order to secure a supply of properly trained forest officers—men competent to administer as well as execute all the complex details relating to forest management, men versed in the best means of administering forest law so that while the immemorial rights of the natives are protected or compensated for, the proper development of the forests in the future shall be secured—recourse had hitherto been had to the forest schools of Germany and France. A certain number of young Englishmen have been trained in these establishments, and, as we have said, their work has been of a satisfactory character and is full of well grounded promise for the future.

Little or nothing, however, has been done at home for the advancement of forest science. When the subject has been mooted we have been told that it was impossible to carry out such a scheme here, as the conditions of our woodlands, the tenure under which they are held, and the legal and fiscal regulations pertaining to them are so different from those of India and the colonies that any instruction that could be given here would be totally inadequate. On the other hand, where forestry has been reduced to a science, and where large areas of forest are under Government control, facilities exist which are not available at home.

Admitting our deficiency we fail to see any valid reason why the deficiency may not be in a very large measure supplied. No one will, we presume, doubt that the general principles which underlie successful forest management can be learnt in London, Edin-

burgh, Dublin, or any other centre as well at Tharandt or Nancy. Vegetable physiology, botany, chemistry, entomology, surveying, draining, road-making, forest laws, and the general details of estate management can surely be as well learnt here as on the Continent. Is it not practicable to devise a scheme of education like that carried out at Cirencester but so extended that it should be available for students in all branches of estate management, forestry, agriculture and horticulture? It is surely not utopian to advocate the formation of one or more universities of this nature in each of the three kingdoms and which would surely prove of immense advantage in the future. When a thorough grounding in the principles of those sciences and arts which underlie all cultural operations of whatever nature have been obtained the pupils might be drafted off, some to the forests, some to the farms, some to the gardens and nurseries, to learn how to apply to the best advantage in practice the principles learnt in the laboratory and college. Practical knowledge can only be gained by practical work, but there can be no question that he who has been best trained in the principles, and knows how best to apply them to new and varying conditions, is likely to be the best practitioner. The thing is so obvious and the necessities of the case are so urgent throughout our great empire, especially in the face of the great competition and the disadvantages under which we now labour, that the time has surely come when a determined effort should be made to bring this matter to a practical conclusion. It is a shame to our boasted civilisation and progress that this matter has not been energetically taken in hand before, and we trust Colonel PEARSON'S paper may tend towards the realisation of a plan the necessity of which all admit, but the practical difficulties of which seem hitherto to have scared our administrators. Whether limited to forestry or taken up on the broader basis we would advocate, we cannot believe that we are a whit less able or less deficient in the means to supply these deficiencies than Germany, France, Belgium, or America with their scores upon scores of forest schools, schools of horticulture, agricultural stations, and the like. If it be not practicable to found new establishments for the purposes we have indicated, let us, at least, turn to better account than we have done the resources open to us in London, Cirencester, Edinburgh, Dublin, and elsewhere. Even in the matter of practical instruction, if we have not the vast and systematically administered forest areas of Germany and France, we have surely sufficient, if properly availed of, to supply a sound practical training which might, if necessary, be supplemented by experience gained elsewhere, and which would enable us to hold our own, and be less dependent on foreign aid.

In the discussion which followed upon Colonel PEARSON'S paper, Mr. THISELTON DYER forcibly pointed out the disastrous results arising from greed and neglect that have rendered some places mere cinder-heaps, and pointed out the great need that exists in almost all our colonies of a carefully regulated system of forest management; and it was satisfactory to hear from General STRACHEY of the desire of the Indian Government to obtain for its forest officers the necessary education in England. "That idea was about to be acted on, and no doubt before long a school would be established here, whether the Home Government joined in it or not." These words are about the most hopeful we have heard on the matter, and we earnestly trust that the General's expectations may shortly be fulfilled.

— THE SEASON'S PROSPECTS. — It cannot be said that the marvellously open and comparatively mild winter has yet created any need for doubt or

distrust, for few are the things which show undue precocity, and, indeed, surprise generally is felt that with such an open time vegetation should yet be so stagnant. This apparent quietude on the part of Nature, however, is one of the most hopeful features of the season, whilst it is also proof that although we have had one of the most open genial winters man can remember, yet we have had others which, if not so even in temperature and pleasant, have yet had softer or milder periods when Nature has been unduly forced and the worst results have followed. Pessimists even now will not allow that such a winter as the present can pass without leaving behind its sting. These will always regard pleasant things in Nature as wasps in disguise, charming humanity with its beauty and then administering a sharp sting, just to remind the too credulous beings that under its sweetness it hides a store of venom. Why may we not reasonably hope that the winter will remain complaisant and the spring will be as delightful. We have had a remarkable winter, and a remarkable spring would be one devoid of keen biting cast winds and sharp white frosts. If the forces of Nature are just now in array in a diverse clime, if the winds prefer to kiss the melancholy Atlantic rather than the ice-bound surface of the Arctic seas, why may not the same mood prevail till the summer sun in all its warmth and glory shall have rendered the winds innocuous? One special feature of the season is the very equable temperature of the soil. It has not been subject to fluctuations of intense frost and of relaxing thaw—changes that seem for the time to hold Nature in the grip of iron, and then to loosen it with stimulating activity. These sudden rebounds in Nature are far more provocative of early growth than is the moderate, even, but comparatively resting temperature such as has marked the present winter. We hear on every hand of the grand promise of the cereals, of the abundance of winter pasture, of the restriction of cattle diseases, and of hopeful prospects for agriculturists. Gardeners may well be not less hopeful, their prospects are good also; the soil works well, seeds are going in well, and in all departments the crops promise well. It is only the croak of the human raven that is heard amidst so much that is bright and promising.

— THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We understand that at a meeting of the Committee of Management, held on Monday evening last, Mr. N. SHERWOOD, of the firm of HURST & SON, Houndsditch, was unanimously elected a Trustee of the Institution, in the place of the late Mr. WILLIAM HURST. With reference to the Pension Augmentation Fund, we are requested to call the attention of the friends of the Institution to the list of collectors published in our advertising columns, and to state that the amount collected was so satisfactory that the committee have decided upon repeating the experiment during the forthcoming autumn. It is also considered that it should be more widely made known that when any subscriber or collector has raised and sent in the sum of 10 guineas he will be entitled to all the privileges of a life subscriber. The total amount of the funded property of the Institution, including £500 raised last summer for the Augmentation Fund, and £800 received from the ARTHUR VEITCH Memorial Committee, is £15,359, leaving the sum of £4650 to be raised by voluntary contributions before the committee will be in a position to increase the amount of each pension by £4 per year. As one objection to the Institution has hitherto been the small amount of the annual pension, we trust the means now taken to remove this may be crowned with success.

— HIBBERTIA DENTATA.—Amongst cool-house climbers which flower during the dull winter months this deserves honourable mention. It is, moreover, a plant of the easiest cultivation. The dark bronzy leaves furnish a striking contrast to the rather large bright yellow blossoms. *H. dentata*, too, does not possess the extremely fetid odour which characterises one or two otherwise very desirable species of the same genus.

— MEZEZEON.—In very many old-fashioned gardens *Daphne Mezezeon* and its white-flowered variety occupy honoured places. Of all the shrubs which "take the wind of March with beauty" probably none can vie with this both in the beauty and the fragrance of its blossoms. As a set-off, however, against this it may be as well to repeat the fact that

all its parts are acrid and poisonous. LINNÆUS speaks of a person having been killed by a dozen Mezezon berries; and in Sweden they are employed to poison wild animals. It is also asserted that Russian and Tartarian women sometimes rub the berries of the Mezezon on their cheeks to produce a slight irritation, which of course gives the effect of rouge, only in a more permanent degree.

— A NEW DRACONTIUM.—A good many visitors to Kew last year could not fail to notice an Aroid of striking appearance and noble size growing in one of the warm compartments of the T range. It attained a height of about 8 feet, and did not look unlike *Godwinia gigas*, as far as leaf was concerned. Like a number of the Aroids, the flowers and leaves of this are produced at different seasons; an infor-

is a very distinct and good variety, purplish-crimson, the margin and tips of the petals white. *Excelsior*, fine light scarlet, quite 7½ inches across, broad well formed petals. Indeed in this matter of good form the Chelsea *Amaryllis* excels all others, if the richness of colouring is taken into account. *Empress of India* is yet in grand form.

— GIANT CYCLAMEN AND PRIMULAS.—There is a grand show of these at the Victoria and Paradise Nurseries, Holloway, at the present time; the plants of *Cyclamen* are very large, and well represent Mr. WILLIAMS' superb strain. There is also a fine lot of *Primula alba magnifica* in flower, as well as the Chiswick Red and rubro violacea, raised by Mr. BARLON, at Chiswick. There is also a fine show of *Amaryllis*, for which these nurseries have long been

Jewish villages of pulling up the root by means of a dog which was killed by its shriek. A very interesting résumé of the superstitions connected with this plant is given in the chapter on "Mystic Plants," in Dr. M. C. COOKE'S recently-published book, *Freaks of Plant Life*. Apart, however, from its history, &c., the Mandrake with its compact tuft of lance-shaped leaves and its numerous rather pretty purplish-tinged flowers, is well worth growing for its own sake. A good specimen of it is now finely in flower in the herbaceous department at Kew.

— HOW THEY MANAGE MATTERS IN BELGIUM.—The *Bulletin d'Arboriculture* contains an account of a *fiête* lately given in honour of M. BOSSAERTS, sub-curator (*sous chef de culture*) of the Botanic Garden, Ghent, on the occasion of the

FIG. 50.—INTERIOR OF WOAD MILL AT PARSON DROVE: THE CRUSHING WHEELS. (SEE P. 335.)

essence has just been developed, and proves that the plant is a new and undescribed one. It was introduced to Kew from the forests of British Guiana.

— MESSRS. VEITCH'S AMARYLLIS.—Again referring to the new forms of *Amaryllis* in flower at the Chelsea nurseries, we may state that Miss Alice Gair is a star of the first magnitude. It received the highest award given to new flowers last year from the Royal Horticultural Society. This really fine flower is nearly 8 inches across; it has fine bold petals of great substance, of a rich scarlet colour shading to crimson at the centre of the petals. Mr. H. Little, also certificated last year, is finely in flower; it is of a purplish-crimson tint with fine broad petals very distinct. *Thalia*, a flower evidently from the same cross, is also very fine. *Iris*, scarlet with broad petals of good form, is a valuable acquisition. *Royal Standard*, also certificated last year, is true to its maiden promise of goodness, as the *Auricula* fanciers would say. It

noted. We also noticed some grand specimens of *Imantophyllum minutum splendens* in full bloom, with many spikes of great strength.

— THE METEOROLOGICAL SOCIETY. — At the ordinary meeting of this Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 15th inst., at 7 P.M., there will be an exhibition of anemometers and of such new instruments as have been invented and first constructed since the last exhibition. During the evening the President, Mr. J. K. LAUGHTON, M.A., F.R.A.S., will give a historical sketch of the different classes of anemometers, and will also describe such forms as are exhibited.

— MANDRAKE. — *Mandragora officinarum* in bygone times has played a very important part in the superstitions of many people. Some belief in its power was evidently current amongst the Hebrews, and JOSEPHUS gives an account of the custom in

twenty-fifth anniversary of his appointment in that establishment. The director of the Botanic Garden and the Professors of the School of Horticulture invited M. BOSSAERTS to a banquet, toasted him of course, and presented him with three magnificent bouquets! A deputation of the pupils of the School of Horticulture offered their congratulations, and one of the number recited a poem in Flemish in honour of M. BOSSAERTS, who was farther presented with a copy of the poem engrossed on vellum within a garland of Roses. After that our system of testimonials seems tame.

— BRITISH GUIANA.—It is intended to publish, under the editorship of Mr. EVERARD IM THURN, a half-yearly journal, to be devoted to the transactions of the Royal Agricultural and Commercial Society of British Guiana, and which will contain papers and occasional notes on agricultural, commercial, geographical, meteorological, chemical, botanical, ornithological,

entomological, anthropological, and literary subjects connected with British Guiana. As an indication of the scope of the journal it may be mentioned that the Editor has already at his disposal papers "On the Indiarubber-bearing Trees of the Colony," by G. S. JENMAN, Superintendent of the Botanic Gardens; "On the Poisonous Principles in Bitter and Sweet Cassava (Janijha)," by E. E. H. FRANCIS, Government Analytical Chemist; "On Cane Soil and Manures," by the same author; "On Cocoa Cultivation in British Guiana," by A. H. HENSON, of Anna Catharina; "On Farming and Irrigation," by the Hon. WILLIAM RUSSELL; "On the Reason why the Red Men of America Tame Wild Animals," by the Editor; "On the Literature of Guiana: being an Attempt at a Complete List of all Works published on the subject," by the Editor; "On the Recent Journey of an Orchid Collector in the Neighbourhood of Boraima," by DAVID BURKE; "On the Best Method of Weighing Canes: a Discussion," by various Authors; "On the Encouragement of Small Industries," by J. S. BLAKE, of Skeldon. A meteorological record will, as soon as it can be organised, form a regular feature in the journal. Lists of the known flora and fauna of the country will be given from time to time, as they can be prepared. A series of vocabularies of the Indian languages of Guiana is also in preparation. Folklore, collected from the Negroes and Indians, will occasionally be given, and many other kindred subjects will be treated. Subscribers in England are requested to send their names to WILLIAM WALKER, Esq., 48, Hilltop Road, London, N. Subscriptions in the colony may be paid to the Librarian, at the rooms of the Society; subscriptions in England may be paid to Messrs. RIDGWAY & SONS, 2, Waterloo Place, London, S.W.

— **FUCHSIA PENDULIFLORA.**—For grouping at exhibitions or private purposes it would be hard to name another variety better calculated to produce a rich effect. The plant is a rapid vigorous grower, bearing long acuminate leaves with a violet midrib. The flowers are freely produced, those from the terminal points hanging gracefully over. Such rich foliage gives a massive appearance, at once taking to the eye and giving tone and substance to an ordinary collection of plants.

— **LINNEAN SOCIETY.**—The papers to be read at the meeting to be held on March 16 are:—1, "The Action of Carbonate of Ammonia on the Roots of Certain Plants," CHARLES DARWIN; 2, "The Action of Carbonate of Ammonia on Chlorophyll Bodies," CHARLES DARWIN; 3, "On the British Salmon," Dr. F. DAY; 4, "Observations on the Breaking of the Shropshire Meres," WILLIAM PHILLIPS.

— **AMERICAN BLIGHT.**—M. PRILLIEUX has made the injuries inflicted by the American blight the subject of study, and has published the results in a pamphlet which has only lately been issued though dated 1879. After describing the insect and the superficial appearances of the injuries it inflicts, M. PRILLIEUX proceeds to investigate matters more closely by describing first the normal structure of the shoots of the Apple. The insect inserts its sucker, composed of three lancets, into the bark so as to reach the cambium between the bark and the wood and where is stored up the greatest quantity of nutritive matter required for the growth of wood and bark. As a consequence the bark is not much affected but the young wood-cells become much enlarged, their walls remain thin and not strengthened by woody deposit, at the same time the cells do not cohere but are disposed loosely so as to form a spongy mass, which ultimately increases so as to cause the bark to crack open, the tumor protrudes, becomes covered over with a corky investment which however offers no sufficient shield either against the insect or the weather; so that when frost comes the spongy tissue is soon killed, dries up, and leaves a cavity in the wood which forms a convenient shelter for the insects during the winter and from which they emerge next spring to renew their destructive attacks upon the new tissue formed at the edges of the wound in the attempt to repair it.

— **THE FROST AND THE PINE WOODS.**—During the two winters immediately preceding the present thousands of *Pinus maritima* planted on hitherto sandy wastes in France unfortunately perished

from the frost. The timber of these trees fetched a very low price, and the turpentine did not flow from incisions in the bark, as in the case of the living tree. M. PRILLIEUX, in investigating this matter, has ascertained that the frozen wood is as rich in resins as that which was not injured, but that it did not flow when the bark was notched, this defective flow being due to an alteration in the cells. The cells of the frozen wood lose their water, become flaccid, and thus exert no pressure on the resin canals as they do in the healthy condition when filled with water. Nevertheless, there is as much water or more in the wood that has been frozen, only it is no longer in the cells, but infiltrated among the tissues in such a way as to produce neither turgescence nor tension.

— **GREVILLEA ACANTHIFOLIA.**—This species was first discovered by ALLAN CUNNINGHAM in peaty bogs on the Blue Mountains of Australia. In general outline its handsome dark green rigid leaves do suggest a resemblance to those of the *Acantbus*. It is a neat-habited bushy plant, and, apart from its racemes of pale purple flowers, is well worth growing for its distinct and striking foliage character. Specimens are now in bloom in the Winter Garden at Kew.

— **WHITE CZAR VIOLETS IN POTS.**—Those who grow Violets in pots for sitting-rooms or other purposes will find in the White Czar a good companion for the common Czar or Victoria Regina, the latter of which makes a splendid pot variety. Violets are always welcome in whatever way they are presented, but as pot plants they are perhaps more enjoyed because not so common as in a cut state. The double white French kind, Belle de Chateaufort, which produces fine large blooms, does fairly well planted out under the protection of glass or even in the open air in a mild climate, but the percentage of ill-formed blooms upon a single plant makes it out of the question to recommend it as a pot variety. A variety to be suitable for growing in pots must be a profuse bloomer, and in this respect the White Czar will make not only a good companion but a very pleasing contrast to other varieties.

— **"EUROPEAN FERNS."**—The last part of this publication (CASSELL & Co.), has lately been issued. It contains, in addition to a full index, for which the readers are, or should be, grateful, a coloured plate, representing various species of *Asplenium* and *Ceterach*.

— **HELIOTROPE WHITE LADY.**—This is one of the best of Mr. CANNELL'S productions, and as seen at Swanley it is the freest flowering variety in a young state in cultivation. A remarkable peculiarity of the plant is that it grows and flowers from a rooted cutting—the flowering apparently being no impediment to growth, and this not only in the case of an exceptional plant or two, but with hundreds in all stages of growth. Even rooted cuttings are flowering freely. Gardeners having much house-work to do will find in this plant a true helpmate. Who ever heard of a gardener having too many sweet-scented flowers in winter? This variety will have a fine effect arranged alternately in jardinettes with some of the purple varieties, say a zig-zag row round the outside, having a suitable object for a centre. Free-growing plants which can be grown from cuttings in a few weeks are those that gardeners can best afford for decorating windows, and if these are sweet-scented they will be more valued than would other plants of much greater intrinsic worth.

— **TURKESTAN PLANTS.**—Dr. REGEL has published a series of descriptions of plants found in Turkestan and Kokan by FEJESCHENKO. Nearly 200 species are described in Latin, with annotations in Russian. An index is given.

— **ST. VILUS' DANCE AND SENSITIVE PLANTS.**—We have constantly new illustrations of the identity in structure between plants and animals, and the close analogy, sometimes amounting to identity, in the life history of the two. One of the latest attempts in the direction is that of Dr. WARNER, the lecturer on botany at the London Hospital, who essays to show that the movements of Sensitive-plants are analogous to those so-called nervous movements more or less unconsciously and unwittingly made by unhealthy children. In plants the movements are, speaking broadly, the result of the sudden afflux of fluid now to this cell or set of cells, now to that, and the con-

sequent "turgescence" of the cells under certain conditions, some of which are known, while others are still mysterious. Dr. WARNER'S hypothesis is that in these ill-nourished or morbid children certain of the cells of the brain are in a condition analogous to those which are implicated in the movements of plants, and consequently that similar results accrue. It may be so, but the movements in the case of the child are far more complex. In the plant the motor machinery, if we may so call it, is at the spot where motion takes place. In the child the machinery is in the brain or spinal-cord, and its influence has to be conveyed to muscles at a distance, just as the "lead" from a magnetic machine conveys the electric force to a distant point and there bursts into light or heat or motion. Dr. WARNER scarcely more than broaches the subject, but it is evident that, to follow up the matter to any useful end, he must take into consideration movements essentially connected with unequal or intermittent growth; and others, such as those connected with the opening and closing of flowers not directly connected with growth. The turgescence above alluded to is supposed by BERT to be due to the large formation of glucose in the cells under the influence of light. This glucose has great osmotic power—a great tenacity, that is, to mix with water or other fluid thinner than itself, in consequence of which a rush of thin fluid to the cells containing the thicker one occurs, and consequent turgescence. The remarkable movements of the side leaflets of *Desmodium gyrans* might be commended to Dr. WARNER'S notice, as their object is at present quite unknown, while their irregular character, and the fact that they are manifested in organs so little developed that they might be called rudimentary, present at least superficial points of resemblance to choreic movements in a child. The following note, taken from the *British Medical Journal*, showing how the movements of an ordinary Sensitive-plant are influenced by good feeding, and how they are increased by poor living, is a point not only of interest to the physician, but also to the gardener, on which account we cite it:—"Three years ago some seed of the Sensitive-plant (*Mimosa pudica*) was set to grow, and at a moist heat of about 90° Fahr. it soon germinated. Before the compound foliage growth had commenced the seedlings were potted off into different earths and sand. Those planted in a soil of two parts of decayed vegetable mould to one of sand grew more vigorously both in height and foliage than the others; and after two months growth they were much less sensitive than others planted in two-thirds of silver-sand and only one-third of leaf-mould. One or two plants were grown entirely in silver-sand. These showed extreme sensitiveness to the slightest touch; even a breath of air, or the slightest jerk of the pot in which they grew caused all the foliage to shut up. Those plants having no nourishment beyond the gases in the air or sand soon turned yellow and died. The plants in two-thirds sand and one-third decayed vegetable mould were not so robust or strong as those grown in a greater proportion of vegetable mould. They failed to produce any flowers, and died off at the lowest temperature to which all the plants were exposed; while those planted in two-thirds vegetable mould and one-third sand fully matured their growth, flowering in a temperature of 50° or 60°, the foliage being of that full green colour denoting the fact that the spongioles of the roots had necessarily been supplied with the various chemical gases in the soil (set free by a due amount of moisture) requisite for producing the continued support of the plants. Their sensitiveness had at the end of August almost left them; indeed, after a blow on the leaf with a twig the foliage would fall, but almost immediately regain its horizontal position."

— **ANEMONE STELLATA FLORE-PLENO.**—What is found in trade catalogues under the name of *Anemone hortensis flore-pleno* is now to be seen in Covent Garden Market, and in the flower shops. It would appear to be somewhat largely grown for cut flowers, the blooms being double and something like those of a small *Chrysanthemum*, and generally of a scarlet colour—some pale and some deeper in tint. Possibly the flowers are brought on in frames, as it would appear to be in bloom earlier than in the open ground. It may be that the exceptionally mild winter has something to do with its precocity. The fact is, the ordinary forms of *A. coronaria* have never ceased to bloom in the open ground during the

winter, and the plants are now producing their flowers in great abundance. The Anemone represents a group of most useful spring flowering plants, commencing with the scarlet *A. fulgens*, and following on with *Apennina*, the varieties of *Hepatica*, *stellata*, *coronaria*, *sylvestris*, and the varieties of *A. nemorosa*. All of them do well in the open ground, and when they become firmly established flourish with freedom and do a rare service in the garden.

— CLASSIFICATION OF POTATOS.—In the *Revue Horticole* is given an abstract of M. HENRY VILMORIN'S classification of Potatos. The main groups are five—yellow, rose, red, violet, and variegated. Each of these five main groups is subdivided according as the tubers are found, elongated, flattened, smooth, or notched. Further points of distinction are to be sought in the eyes, which are violet, yellow, rose, or white, and in the colour of the flowers—grey, lilac, white.

— CAMELIAS AND HYACINTHS.—On Wednesday Messrs. WILLIAM PAUL & SON, of Waltham Cross, opened an extensive and very interesting exhibition of Camellias and Hyacinths, &c., in the Royal Botanic Society's Garden, Regent's Park. Intending visitors should make a point of going early in the ensuing week.

— SEEDLING POTATOS.—The judging of seedling Potatos by the International Committee at the Exhibition of September 20 and 21 is intended to be as thorough and comprehensive as possible. Raisers of seedlings will find the terms stated in the schedule under classes P, Q, R, S, but it may prevent mistakes and disappointments if we at once endeavour to state the case clearly. An intending exhibitor must at once forward "a sufficient number of tubers of each variety" to Mr. BARRON, Royal Horticultural Gardens, Chiswick, and a memorandum on the subject to the Secretary of the International Potato Exhibition, 23, Upper Thames Street. The judges will require to have before them on September 20 a dish of nine samples of each competing seedling, and an extra parcel of six for cooking, and as a matter of course these should not be exposed to the light in any way. The judges will act on the report as to cropping, on the report as to tasting, and on the appearance of the exhibition samples. The object of all this trouble is, of course, to render the final decisions as much as possible beyond question, and of real public importance.

— THE WEATHER.—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending March 6, issued by the Meteorological Office, London:—The weather has been very unsettled and dull, with rather heavy rain in the south, and rain, snow, or sleet in the north. The temperature, though lower than during last week, has still been above the mean in England and Ireland, but in Scotland it was slightly below. The thermometer was generally highest on the 5th or 6th, the maxima ranging from 51° in "Scotland, W." to 55° at some of our south-western stations, and 57° at Hereford. The minima were lower than of late, and varied from 27° in the "Midland Counties" to 35° in "Ireland, S." The rainfall has been more than the mean in all districts, the excess in the west and north-west being rather large. Bright sunshine shows a decrease in the extreme north-east but an increase elsewhere. The percentage was greatest (38) in "England, S.," and least (11) in "England, N.W." Depressions observed:—At the commencement of the period the barometer was rising in all parts of our area, with moderate southerly or south-westerly winds; but by 8 A.M. on March 1 the mercury had fallen rapidly, and an irregularly-shaped area of low pressure, around which were steep gradients, was shown over England and Ireland. This disturbance caused at first strong easterly winds or gales in the north, and fresh or strong westerly gales in the south; but as it slowly filled up the force of the wind gradually abated, and by the evening of the 3d had become very light from the east on all our coasts. From the 4th until the close of the period the barometer was highest in the southern part of our area, while depressions travelled in an easterly direction across our northern coasts, giving us south-westerly to north-westerly winds, which occasionally increased to a strong breeze or fresh gale.

HOW TO DISTINGUISH ORCHIDS OUT OF FLOWER.*

In the *Gardener's Chronicle*, n.s., xiv., p. 750, there is a translation of an analytical key to the vegetative characters of various Orchids and groups of Orchids, originally published by Dr. Pfitzer in the *Verhandlungen des Naturhist.-Med. Vereins zu Heilberg*; and in an introductory note thereto most of the technical terms there and here employed are explained. What is there set forth in a tabular form is elaborated and illustrated by additional examples in the book before us. Ignoring altogether the floral characters, Dr. Pfitzer attempts to construct a comparative classification or subordination of Orchids from the characters afforded by their vegetative

characters according to their vegetative characters than does the abstract referred to above. It might have been expected that the author would exhaustively examine the results obtained, and have indicated how far they might be used in conjunction with the characters of the floral organs in a systematic classification of the order; but he has not done so. Neither has he attempted the classification of all the species of a single large genus. What he has done is to study a number of species of various genera—as many, it may be presumed, as offered sufficient materials—and to construct a framework of a classification from their vegetative characters. It is not clear what value the author himself attaches to his work, or how far he anticipates that characters of the vegetative organs can be utilised in a systematic classification. At p. 7

FIG. 51.—AERIDES SCHROEDERI.

An example of a monopodial Orchid, in which the main stem continues to grow at the point, the inflorescence shoots being given off at the nodes from the axils of the leaves.

organs—that is to say, their stems, leaves, and inflorescences; but partly in consequence of the great value of living plants of many species, partly in consequence of many species and genera being only known from portions of plants preserved in herbaria, this classification, as the author acknowledges, though embracing all the tribes of the order, is fragmentary and incomplete. Nevertheless, it may serve as a basis for further researches in the same branch of knowledge, and the author has done well to publish the results of his labours at once, instead of delaying it until he could fill up the gaps. At the same time, it is disappointing to find that this massive quarto volume contains nothing nearer finality in the classi-

fications than Mr. Denthon, in his essay on the tribes of the Orchideæ,* makes no use of the abstract published in this journal and elsewhere, from which it might be inferred that he considers use might have been made of it. At p. 8 he distinctly states that he would not think of classifying Orchids by their habit alone; yet he does not say how far he would go. We are left to determine how far this is feasible as best we may from the body of the work.

With regard to the genera *Bletilla*, *Prepanthe*, and the relationship of *Phaius*, *Calanthe*, and *Limodorum*, alluded to at p. 4 as instances of Orchids closely allied in vegetative characters, and even in their floral characters, except the pollinia, it may be mentioned that *Elime* and *Denthon* have stated that *Bletilla* and *Prepanthe* were separated from *Bletia* and *Calanthe* respectively, owing to a mistaken view as to the nature of their pollen. And Mr. Denthon would

* *Grundzüge einer vergleichenden Morphologie der Orchideen* (Outlines of a Comparative Morphology of the Vegetative Organs of the Orchideæ). Von Dr. Ernst Pfitzer, O. Professor der Botanik an der Universität Heidelberg. 4to, pp. 191, with one coloured and three uncoloured plates and thirty-five woodcuts. Carl Winter's Universitätsbuchhandlung, 1882.

refer *Limatodes rosea* to the genus *Calanthe*, hence, if this view be correct, a hybrid between the former and *C. vestita* is no very extraordinary phenomenon. In these instances it appears to have been proved that the supposed differences in the pollen did not exist, therefore there can be no justification for establishing new genera, and placing them in different places in the system. But now with reference to the value of vegetative characters in classification it seems pretty clear that, although the great divisions of flowering plants (dicotyledons and monocotyledons) are with some few exceptions distinguishable from each other by evident vegetative characters, yet generally speaking vegetative characters cannot be employed in the successive divisions until we come to the subdivision of genera. Judging from Dr. Pfitzer's results this holds good for Orchids, as well as other families of plants. We are not losing sight of the fact that certain orders, sub-orders, and tribes are characterised by habit as well as floral affinities. But very little investigation teaches us that certain vegetative types—physiognomical types, they might be designated—are repeated in numerous natural orders of the most distant affinities, showing that they are the outcomes of external conditions, such as climate, medium, and associations. We must, however, be careful to distinguish between purely physiognomical modifications of vegetative organs, and those that coincide with or accompany the genetic affinities. Dr. Pfitzer recognises the fact that certain vegetative Orchid types are repeated in genera possessing widely different floral structure; but he also states that his primary vegetative characters are genetic rather than physiognomical. He primarily divides Orchids into those which grow continuously in one direction (monopodial), and those in which the growth is arrested at one point and continued from another (sympodial). These definitions, if not absolutely exact, are sufficiently so for all practical purposes. Monopodial Orchids have stems which lengthen indefinitely at the tip, season after season, and bear lateral inflorescences, as in *Acridis Schroderi* (see fig. 51). In sympodial Orchids the growth of the main axis soon ceases, usually at the end of the growing period, and a lateral shoot continues the further development. The first is a comparatively small group, comprising, as far as at present known, most of Bentham's sub-tribe *Sarcanthes*, the American genus *Dichena*, of the sub-tribe *Maxillarieae*, and the widely-spread Neotropical genus *Vanilla*. The genera *Vanda*, *Renanthera*, *Sarcanthus*, *Acridis*, and *Phalenopsis*, belong here, and mostly inhabit Africa and Asia. The sympodial Orchids are again divided into two groups, the *Pleuranthes*, and the *Acranthes*—in other words, into those having lateral inflorescences, as *Dendrobium*, *Oncidium*, and *Angraecum Scottianum* (fig. 52), but not in other *Angraecums*, and those in which the inflorescence terminates the stems, as in *Epidendrum*, *Cypripedium*, and *Cattleya* (fig. 53). For further particulars we must again refer the reader to the abstract, *ante*, vol. xiv., n.s., p. 750. That abstract, or key, has a somewhat formidable appearance, but it is very simple when we know that the plan of its construction is a succession of contrasted characters. Thus, in tracing out the affinity of a plant, supposing it has not the character of I., we pass on to H., and under that, if it has not a lateral inflorescence, as defined under A., we pass to B., and so on. Incomplete as it is, the key contains a vast deal of information respecting the vegetative organs of Orchids in a small space; and, although in no case do the primary and secondary divisions correspond to the whole of a tribe or tribes, yet the ternary division leads us to the *Ophrydeae* and the *Neotieae*, and, what is of more importance, to large genera. But, as we have already stated, we anticipate greater usefulness from the characters afforded by the vegetative organs in the subdivision of genera and in the description of species. Practised nurserymen are able to distinguish species and varieties of shrubs and trees by their vegetative characters to an extent that seems unattainable to the beginner, but such knowledge could never be learnt from a book, even if it could be put into words, and it is not likely that descriptive vegetative characters alone will lead to the identification of Orchids. We have little space left to notice Dr. Pfitzer's concluding chapters on the habitats and mode of life, &c., of Orchids, &c., but it may be mentioned that one of the points upon which he most strongly insists is, that Orchids, with comparatively few exceptions, love the sun, and would

thrive better under cultivation were they not shaded so much. In the circum-scription of the genera Dr. Pfitzer follows Mr. Bentham, but it would have been better in the references to have cited the names employed in the places to which reference is made. Thus at p. 21 we are referred to the *Gard. Chron.*, n.s., 3., p. 478, for the dimensions of a plant of *Stenopis lissochiloides*, Benth., which is very perplexing, if the reader has overlooked the fact, recorded at p. 14, that *Vanda Bateana* (*Plethia lissochiloides*) is a synonym, as that is the name used in the place referred to. In the same way *Vanda Cathcartii* becomes *Arachnanthe Cathcartii*; and in the index Blume's genus *Arachnanthe* is inadvertently attributed to Reichenbach. *Vanda Loweii* (*Renanthera Loweii*) should also have been referred to *Arachnanthe*. One word with regard to the title of the book. As it stands it is misleading, and needs the qualification expressed by the words "of the vegetative organs." The work is copiously illustrated with woodcuts, most of which have appeared in these columns, and of which due acknowledgment is made, *H. E. Hemley*.

have by sending for it and paying the carriage. I finally got it when it had been in her keeping for three days. *C. Wally Dod, Edge Hall, Malpas, March 2.*

Stephanotis in Fruit.—We have a plant of *Stephanotis floribunda* that has been planted out for several years, and has always flowered freely, but never till now has borne fruit. It has one about the size of a turkey's egg, and like a Plum in shape. I shall be glad to know whether any of your correspondents have ever fruited it. [Yes; many of them. Ed.] *J. Baylis, Leiston Old Abbey, Suffolk.*

To Prevent Birds from Eating Fruit-Buds.—Reading Mr. Grieve's excellent article on the Gooseberry in your last issue it occurred to me to make known to you the plan I adopt here to preserve the buds of Gooseberries, Currants, and Plums from the depredations of birds. As soon as the attack on the buds begins the whole of the bushes and trees are at once pruned, and a large quantity of lime wash is prepared sufficiently thin to admit of its passing through a coarse syringe. With this a man follows the pruners, squinting it plentifully over both bushes and trees. If done on a dry day it dries in two hours, and no

FIG. 52.—*ANGRAECUM SCOTTIANUM*.

An example of a sympodial Orchid: the main stem here ends in an inflorescence which bends downwards, and so appears opposite to a lateral foot in the axils, while the originally side-shoot becomes terminal, and continues to grow in the direction of the main stem.

HOME CORRESPONDENCE.

Continental Express Parcel Post.—Some of us have been looking forward to this as likely to give long-desired facilities for getting a rapid delivery of parcels of fresh plants from distant parts of Europe. I may say that it is an arrangement concerted between the chief European Continental states, by which parcels under 10 lb. in weight should be carried at a cheap rate as quickly as letters, and that it came into operation on the first day of this year. But nothing seems to have been done in England to enable us to derive any advantage from the arrangement. A parcel stated on the address to be plants, and requiring immediate delivery, was sent to me from Erfurt last week. It seems that the English agents for the Continental Parcel Post are not, as one would suppose, the Post-office authorities, nor any large railway company, but a firm of private carriers. The parcel was handed over to them fully and very legibly addressed to me; it was then forwarded to the local agent of these private carriers, a woman who keeps a small fancy shop at a country town 9 miles distant from me. She wrote to me by post saying a parcel had arrived for me from Germany which I might

amount of rain will then wash it off, neither will any bird even perch on bush or tree. Four years ago this winter I walked about in hand from morn till eve day after day to keep the butterflies in check, as I had planted a great many young bushes and Plum trees; but the birds, in spite of me, cleared every bush, so that they were only skeletons when spring came. Ever since I have used lime wash, as stated above, and have no trouble in securing immunity from birds. *W. Armstrong, Ford Manor.*

Pendell Court.—Amongst the many novelties in the houses at Pendell Court (Sir G. Macleay's), Eltchingley, worthy of notice now, is a fine specimen of *Cotone arabica*, about 9 feet high and 6 feet through, which is bearing a fine crop of berries, some of the shoots having over fifty berries, which come in threes and fours from the axis of the leaves. Also a grand specimen of the noble *Platyterium grande*, which measures over 5 feet in diameter, and is in splendid condition. The lovely *Cania iridiflora*, var. *Ehmanni*, is still in flower; it is nearly to feet high, and has fine spikes of its bright crimson flowers; it has been in bloom over seven months. The rare and beautiful fine cut-leaved *Anemone nemorosa* is just opening its flowers; a new *Asplenium platyneuron* is very distinct, and will prove to be a lovely greenhouse

Fern; this was recently shown by Mr. Green, and worthily received a certificate; the old *Cineraria cruenta* is also grown, it is seldom seen, but is a gem for cutting from. The houses contain many plants seldom met with, and which, under the care of Mr. Green, are sure to succeed. *A. O.*

Mice in Gardens.—We were sadly pestered with mice in the garden last spring until a friend of mine caught a grey owl, which he gave to me. I got a box made for it, and placed it in one corner of our walled garden, merely clipping one wing before letting it go. Within a month there was not a scratch of a

putted up in the autumn, and put into gentle heat, it will come into bloom early in January. *H. C. O. G.*

Ants in Peach-houses.—Having been troubled with ants very much in one of my former places, a few words respecting the plan we adopted to clear them out may not be out of place. Treacle no doubt is a very good thing to attract them, as Mr. Riddell informs us. But our plan was to plunge saucers in the borders up to the rim, with a piece of sponge dipped in sugar placed in each one, also a piece round the stem of each tree. The ants would gather in hundreds and feed on the sugar, then conceal themselves

believe my eyes, I pulled it up to send to the Editor of the *Gardeners' Chronicle*, which I have done. On examination I think that one of the small root-balls has come up exactly in the hollow centre of the dead stalk, and having grown through the tube has produced the curious appearance described. Is it so? *C. Valley Dot, Edge Hall, Malpas, March 5.* [Yes: the length of the dead hollow stalk through which the young plant has passed being no less than 5 inches. *Ed.*]

Plant Labels.—Having read with interest the discussion about labels, I send you one for your in-

FIG. 53.—*CATILEVA GIGAS.*
An example of a sympodial Orchid with terminal inflorescence

mouse to be seen, and I have not seen the sign of one since. *C. Lucas, The Gardens, Belmont, Taunton.*

White Broom for Forcing.—The White Broom, *Cytisus albidus*, is a great acquisition in conservatory decoration, and requires but little heat and ordinary attention to bring it into bloom at a season when flowers are rather scarce. We have had a large plant of it in splendid flower for the last six weeks, and it looks so fresh at the time of writing that I imagine it will last fully six weeks longer. Others may have forced this Broom successfully for many seasons without thinking it worth while to bring it into prominent notice; but those who have not done so, and who wish to have a good show, would do well to give it a trial. If

in the sponge; then by going round several times during the day with boiling water and shaking the ants into it we soon cleared them out of the houses. *A. M., Dorset.*

Lilium Leichtlini.—As might be inferred from Mr. Elwes' picture of it, this seems to be a very prolific Lily. It was the first to appear above-ground in a cold frame I have had made to grow Lilies in free soil. A bulb which made two flowering stalks last year has already sent up twelve shoots, the strongest being a fortnight old and 6 inches high. The most remarkable circumstance about it was that the old stalk, cut off 4 inches above the ground, seemed to be breaking at the end into new growth. Not being able to

speculation. I use them for my herbaceous plants, and they answer admirably, and are almost indestructible. They have a great many good qualities; snails will not run away with them, and magpies have not as yet taken them to line their nests; they are not likely to be dug up or in, and any one can fit the wire to the label. *Edward Morris, The Nurseries, Epsom.* [The arrangement of stout galvanised wire with a loop at the top, on which hangs a zinc label. *Ed.*]

A Remnant of a Submerged Forest.—On the east coast of Sutherland, at a point about half a mile westward from Golspie, the recent storms have laid bare at low water the edge of a field of peat, from 6 inches to 1 foot in thickness, and extending about

100 yards in length along the shore at the level of low-water mark. Attention was first attracted to it, by large pieces of peat being found thrown up on the beach near high-water mark by the action of the tide after some of the recent storms. Examination of some of the pieces shows the remains of trees and roots of considerable size. The wood is not in any way petrified, but is rather soft when first taken out, and of a reddish colour, and bears evidence of having been at some period or another subjected to considerable pressure. Many of the smaller branches, from 1 to 2 inches in diameter, may be seen as flat as ribbons, nothing of the wood remaining now, but simply ribbon-like pieces of bark. Small seeds have been found in some of the pieces, also Hazel-nuts in fair preservation, and many wing cases of small beetles. Three kinds of trees have been made out by the wood and bark—viz., the Birch, the Alder, and the common Hazel or Filbert. Some of the members of the Sutherland Field Club visited the place, with a view of finding out the overlying strata, and tracing the peat bed, if possible, from the point where exposed for some way inland. The incoming tide and the appearance of water before the peat field was reached prevented anything being done in the way of ascertaining its extent. Some of the first trials, about twenty paces from low-water mark, showed that the peat was overlaid by a deposit of blue clay about 1 foot in thickness, the blue clay being in turn overlaid by about 6 inches of yellowish sandy clay, gravel and sand forming the remainder between the yellow clay and the surface. No shells were found in the yellow clay, but the blue clay was thickly studded with the commoner bivalve shells usually found on the sea coast. One thing is clear, a forest once flourished on this part of the bed of the Dornoch Firth. When and how it came to be submerged is a matter for geologists to crack. *D. McNeill, Dunrobin Castle Gardens.*

A Monster Wistaria.—To all lovers of this beautiful climber there may be seen at the present time, at the seat of W. Young, Esq., Valence, Westerham, Kent, a magnificent old plant covered with pale lilac blossoms. I thought it might be of interest to quote a few of its dimensions. At the base its circumference is exactly 4 feet, and at 6 feet from the base it measures 3 feet in circumference, from which point there extend two immense limbs, travelling to the whole of the conservatory, at a distance of 140 feet, besides its numerous minor branches. The sight presented before the visitor, and the agreeable fragrance with which it fills the whole house, is one never to be forgotten. It is well worthy a visit, and may be viewed on application to the gardener, Mr. Haffenlen. I may mention that the same variety was planted outdoors in the same year, and trained to a wall, but the dimensions are not a quarter of this indoor-cultivated one. I should be glad to hear from your readers if there is another such a fine specimen in the country. *A. O. Watkins, Westerham.*

The Tenby Daffodil.—This Daffodil, which grows wild at Tenby, whence I had it and name it, was the first of the genus to flower in my garden this year, having come into flower on February 25—two days before the first flower of *Narcissus nanus*. The latter, however, came into flower all over the garden at once, whilst the Tenby Daffodil comes in a long succession, each individual flower lasting longer than those of any other variety of *Narcissus*. Mr. Peter Barr told me last year that less is known about the origin and history of this Daffodil than any other. He calls it *N. obvallaris*—for want, as he said, of a better name. In Sowerby's *English Botany* it is called *Broomfieldi*. Mr. Barr also told me that it is unknown in Continental nurseries, and that he went to one at Holland without meeting with it. It may once be distinguished by the shortness and stiffness of the outer segments of the perianth, the tube, which is wide and open, projecting far beyond them. It is the only variety except *nanus* which regularly ripens seed in my garden; and I have this year tried to cross it with *Horsfieldi* and *Empress*, which I have forced for the purpose. With the same treatment these two came into flower on the same day, *Horsfieldi* having, as usual, the larger flowers of the two, but *Empress* being taller; *Horsfieldi* seems to me to produce no pollen. *C. Wolley Dod, Edge Hall, Malpas, March 8.*

United Horticultural Benefit and Provident Society.—In your notice of this Society last week an important feature of the Society is omitted, and that is, what becomes of the members' annual contributions to the benefit fund after the share to the sick pay is deducted. This is placed out at interest by the Society in some safe investment, as allowed by the Friendly Society's Acts of Parliament. I notice the owners of this fund meeting at 10 o'clock. It may be this day received my annual balance-sheet, and by it I see my share towards sick pay for the past year was "fivepence," and the balance due to me in the society's books, £34 17s. 3¼d. I may say that I am the first member on the books, although there are

several others about the same date. This money goes on accumulating year by year, until the member dies or attains the age of seventy years, when if he wishes he can withdraw it or allow it still to accumulate. This will explain why there is no "burial fund." The Secretary will gladly give any further explanation, and send copies of rules of this useful society. Young gardeners especially will find it a good and safe investment. *William H. Heale, 16, Simpson Street, Newcastle-on-Tyne.*

Foreign Correspondence.

HORTICULTURE IN SWITZERLAND.—Our little country is often considered behindhand as regards horticulture. It is true that gardening pursuits do not take so important a place with us as they do in Belgium or Holland, countries in extent as small as Switzerland. We have also few specialities in the way of cultivation. This arises no doubt from the nature and configuration of the soil and its sterility over large areas. In the alpine districts horticulture carried on as it is in the plains is impracticable. Nevertheless, when the necessary allowances are made it will be found that we are in no wise behind our neighbours. It must be borne in mind that there are in Switzerland three distinct stocks or races of people welded into one common country. The cities of Geneva and Basle are cosmopolitan, but German Switzerland, with Zurich at its head, receives its impulse from Germany. Latin (Romande) Switzerland, which borders upon France on one side and Italy on another, adopts the cultivation pursued in France, especially in the matter of fruit tree culture. Attention is here chiefly directed to what may be grown out-of-doors, while in German Switzerland stove plants, window plants, the manufacture of bouquets, &c., attract most attention.

In Italian Switzerland, which is, though politically Swiss, geographically Italian, the customs of Italy prevail. German Switzerland possesses numerous and important commercial horticultural establishments, of which the most notable is that of MM. Froebel, of Zurich. All branches of the nursery trade are carried on there, but special attention is given to the cultivation of plants under glass. With us at Geneva our largest nursery establishment is that of MM. Vaucher & Cardinaut, who have a reputation for hardy trees and shrubs, Conifers, and specially for fruit trees. It is well known that we have at Geneva the two finest Cedars of Lebanon, brought by Jussieu, and planted by him at Beaulieu about the same time as that in the *Jardin des Plantes* at Paris, which, however, is not nearly so fine a specimen as those at Beaulieu. In the neighbourhood of Geneva are several fine old gardens. In the time of Voltaire, who resided in one of the suburbs, there was much taste shown in the laying out of gardens. At Geneva, also, was established the first botanic garden in Switzerland under the auspices of our illustrious fellow-citizen, M. de Candolle. At Geneva, also, under similar auspices, was established the first Swiss horticultural society, in the year 1855. It publishes a journal, which is greatly esteemed by the members and by the fellows of corresponding societies, and by its exhibitions has contributed greatly to the development in this country. It has a rival even in Geneva, which numbers 500—600 members, and the existence of these two societies side by side in our little centre may be taken as an indication of the prosperous state of horticulture. In this respect Geneva surpasses most of the towns of Europe of equal size. There are two horticultural journals in Geneva, the *Revue Horticole* of M. Vaucher, and the *Jardinier Suisse*. In German Switzerland there are only certain horticultural periodicals of minor importance, and exhibitions and horticultural societies are few and far between. The Canton de Vaud has its horticultural society, numbering many members, and publishing a journal which brings up the number of publications in French Switzerland to four—not an insignificant number, all things considered.

The only special characteristic of Swiss horticulture is the cultivation of alpine plants. Throughout Switzerland, whether the people be of Romande or Germanic race, there is a strong taste for mountain excursions. It is, therefore, not to be wondered at that the flora of our mountains is appreciated by a large number of our citizens. For many years the cultivation of alpine plants in the plain has been carried on at Geneva, the city of botanists and of students of alpine natural history; but it is only

within the last ten years that the cultivation of these plants has been taken up as a branch of trade. Messrs. Froebel were the first to undertake this department on a large scale, and many others have since followed suit. With this exception, we have no speciality in Switzerland, and no parks and pleasure-grounds on the scale of those in England; but so far as we can we have imitated the taste and procedures of our masters, and we may safely say that horticulture in Switzerland has already a well-defined position, and a future full of promise. *H. Correvon, Inspector of the Botanic Garden, Geneva.*

CAMBRIDGE, MASS., U.S.A.—The Horticultural Society of Boston, Mass., held an exhibition on February 18 in the Horticultural Hall, a noble stone building, very solid and ornamental from top to base. The library is extensive, and open at all times to all members. Boston, in this respect, puts London to shame. The Society is a sound affair, not in debt, and managed by practical men, who put life into it. The meeting was well attended by about 200 members, though the country was clothed in a sheet of snow about 18 inches deep. Mr. C. M. Hovey had a group of cut Camellias, C. M. Hovey and Mrs. A. M. Hovey being the best; and a similar group came from Mr. F. B. Hayes, Lexington. Two pots of fine Mignonette came from Mr. Atkinson, gr. to Mr. J. L. Gardener, of Brooklyn. Some good Lettuces came from Mr. Waize. From Mr. Ward, of Salem, came the grandest bunch of *Marchal Niel Rose* I ever saw—such, indeed, that Mr. Paul might covet. A paper was then read by Mr. Philbrick on "Garden Vegetables." The paper was good practical matter, and a discussion followed, the leading points brought out being that deep culture, plenty of manure, and good selected seed should be used. English Cauliflower seed was spoken of as not to be depended upon. The Council and the members freely mixed, not as at South Kensington. Such discussions, as you have often urged, would give interest and value to Kensington meetings.

When the ordinary business of the meeting was over, Mr. H. J. Veitch, of Chelsea, London, a well known horticulturist, was elected a corresponding member.

I have seen some of the best gardens in the neighbourhood of New York and Boston. The Americans are coming along, though they have none of the old establishments as in England, yet they like gardens, and are, in my opinion, men of letter taste than most English people. In the windows of New York and New Jersey and Boston you see Agaves, Opuntias, Calas, Crassulas. In all gentlemen's places I have seen, Agaves and Cacti are more numerous than Pelargoniums. Mr. Pelargonium-Society-man would go mad on here. In one of the largest and best kept gardens of New England the gardener, Mr. Harris, said he only wanted about 24 pots for his cuttings, but he had about 100 Agaves. Mr. John Hoey, of Long Branch, N.J., has two houses, 300 feet long, devoted to a splendid collection of Cacti, Agaves, and such things; also Palms, Dracenas, Crotons, Ferns, Orchids, and general stove and greenhouse plants in profusion. Here, as in all gardens I have seen, they grow Roses, and quantities of *Myrsiphyllum asparagoides*, on wire, for decoration. Mr. Rathlun, of South Amboy, N.J., has a fine lot of Orchids, Crotons, Cycads, Cacti, Agaves, &c.

At Messrs. Pratt's, Watertown, Mass., I saw Orchids well done, Crotons, Dracenas, Agaves, &c. Here I saw some splendid canes of Black Hamburg Vines; Grapes grow well here, as do also Violets. The sun is as bright as in England in June, but in one night the thermometer fell 50°; what do you think of that? They don't look at the kitchen garden for about four months. Bays, Rhododendrons, Hollies, Azaleas, &c., are kept in winter in a pit underground, with a wooden floor, and a few lights on the top; they keep well so, and are planted out in spring. Oaks, Abies excelsa, Maples, Juniperus virginiana, Abies canadensis, Larch Firs, are most planted. Abies excelsa is used for making hedges, and good ones they are.

At Mr. Hunnewell's, Wellesley, Mass., I saw a fine lot of *Phalenopsis* in flower as good as in England; *Bougainvillea* does splendidly here. I saw here also a splendid lot of new Dracenas; Aloes, Yuccas, Cacti, Baccararas, and other succulents were plentiful and good; *Calanthes* and cool Orchids are well done, and *Cypripediums*.

At John L. Gardener's, Brooklyn, Mass., I saw

SEEDS.
LONDON: March 8.—There is now an active consuming demand for farm seeds. Stocks being unprecedentedly light, the tendency of values is upwards. Alsike, white, and French, are dearer. American Clover seed is firm, shipments continuing on a moderate scale. An advance on the price of Sainfoin has been established at 2s. per quarter. More money is also asked for Lucerne. Just now there is a great scarcity of spring Tares. Winter Vetches are still in brisk request. Bird seeds are dull. John Sharp & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.
At Mark Lane on Monday business opened very quiet, but eventually there was rather more doing than on Friday, at about 12, decline for 2000 Wheat; on inferior qualities the decline was greater. Flour was dull, and prices, except for fine qualities, were mostly 1s. per sack lower. Maize was quiet on the spot. Barley was about 3d. lower for grinding sorts; Beans and Peas were quiet and unaltered, and new Oats were the firm lower. On Wednesday Wheat net little inquiry, and the tendency of prices was against sellers. Maize was steady at Monday's rates, and Barley very firm. For Beans and Peas prices were unaltered, and the demand for Oats was very slow.—Average prices of corn for the week ending March 4.—Wheat, 41s. 7d.; Barley, 30s. 8d.; Oats, 21s. 8d. For the corresponding period last year:—Wheat, 41s. 7d.; Barley, 31s. 7d.; Oats, 21s. 2d.

CATTLE.
At Copenhagen Fields on Monday the beast market was fairly supplied, and the trade steady at about the rates of Monday's slaughter. Sheep were very short, and brought in many cases enhanced rates. Prime calves were scarce and dear. Quotations:—Beasts, 4s. 2d. to 5s. 2d., and 5s. 6d. to 6s.; calves, 5s. to 6s. 10d.; sheep, 5s. 6d. to 6s. 5d., and 7s. to 7s. 10d.—Thursday's trade, though not active, was dear. Beasts sold slowly at extreme quotations, and fully late rates were paid for sheep. Calves remained scarce, and pigs were firm.

POTATOS.
The Borough and Spitalfields Markets reports state that there were good supplies and a moderate demand at the following quotations:—Scottish Champions, 50s. to 60s.; ditto Regents, 70s. to 80s.; ditto Marston Boningtons, 10s. to 9s.; flukes, 120s. to 110s.; and Victorias, 110s. to 120s. per ton. German reds, 3s. to 4s. per bag.—The imports into London during the preceding week were 10,583 bags from Hamburg, 1200 cwen, 97 Houghog, 403 Brocous, 105 Harbgen, 66 tons Lauterback, and 123 tons from Rouen.

COALS.

THOUSANDS IN USE.
 SENT CARRIAGE PAID.
 MONTH'S TRIAL ALLOWED.
 NO CHARGE FOR PACKING.

THE BEST GENERAL PURPOSE MACHINE.

The "AUTOMATON" Lawn Mowers are thoroughly strong, well-made, and durable machines, and the best suited for general work and *Gardener's* use. They cut the grass perfectly, leave no ruts, but produce a smooth velvety surface on the Lawn, and are light in draught.

The "AUTOMATONS" have front rollers for general work, and side rollers for cutting long grass, or when it is unnecessary to roll the grass in front of the cutters. They have the best machine made gearing, the best self-sharpening knives of steel and iron rolled together, and automatic silent drivers.

RANSOMES' LAWN MOWERS
 ARE THE BEST.
 MELBOURNE EXHIBITION, 1880. THE HIGHEST AWARD.
 COMPLETE PRICE LISTS FREE BY POST.
 STOCK KEPT IN LONDON at Arch 92, Spitalfields Station, Bethnal Green, E., and Machines may be ordered from any respectable Ironmonger.
 Ransomes, Head & Jefferies, ORWELL WORKS, IPSWICH.

THE "WORLD."

The "GLOBE" (late "GLOBE") Lawn Mowers are intended for cutting long grass; and, whilst similar to the Lawn Mowers imported from America, have the special advantages of the more accurate fitting and general durability of English manufacture and perfect adjustment.

The "WORLDS" will cut wet, dry, long, or short grass without clogging, and cut off almost all the "beats." They leave the surface smoother than similar machines, and are well adapted for getting over a large amount of work with little labour.

FOR CUTTING LONG GRASS.

"ARCHIMEDEAN" AMERICAN LAWN MOWERS.

HIGHEST PRIZE

At the PARIS EXHIBITION, 1878:
 And the Jury, in their Report say—"The 'ARCHIMEDEAN' did the BEST WORK of any Lawn Mower exhibited."

"THE COVENTRY."

(REGISTERED).

NETTLEFOLD & SONS desire to call especial attention to their "COVENTRY" LAWN MOWER, which they can confidently recommend as the best and cheapest in the Market.
It has all the improvements which have of late been introduced into this class of Machine, either in England or America; and for the manner in which it does its work, its lightness, and its ease with which it can be used, cannot be surpassed.
Its cheapness brings it within the reach of every one, and in this respect it defies competition with any American machine before the public. It is made, as it name implies, at Coventry, by skilled English workmen, and of best English Steel and Iron.
These Machines can also be supplied with **ROLLERS AT SAME PRICE, and GRASS BOXES** at a small extra cost.

MANUFACTURED BY

PROTECT YOUR PLANTS.
"FRIGI DOMO."
Registered Trade Mark.

"Horticultural Society's Garden, Farnham Green."
"FRIGI Domo" is now largely employed here as a protecting material instead of mats. All houses and pits to which it can be usefully applied are covered with it at night, and it is found to give entire satisfaction. It lasts longer than mats, is cheaper, and keeps out frost equally well.

"Broom House, Fulham."
"FRIGI Domo"—After two winters' experience of this material as a protection from frost, I have come to the conclusion that it is the best covering for pits and frames which ever came under my notice. It will keep out more frost than two mats, while it only costs the price of one; it is more tidy than loose litter, and fits more closely than straw hurdles, and it is much more manageable, for when fitted on to a roller and way, covering and uncovering can be effected in half the usual time, and there is no danger of breaking the glass. In wet weather it lies quite close to the glass, but as soon as frost sets in it becomes almost as tight as a drum, thus forming a space between it and the glass, a thing very desirable where the edges fit tightly, which they do. I believe that any greenhouse plant is perfectly safe under it until the thermometer indicates 10° of frost.—J. RUST."

To be had of all Nurserymen and Florists.

COWMAN, or STOCKMAN.—Three children (youngest age 12); Wife can Manage Dairy or Poultry. Can have four and a half years' good character.—A. HERBERT, Silverlants, Chertsey, Surrey.

EPPS'S
COCOA.
AND
COMFORTING.
"By a thorough knowledge of the natural law which governs the operations of digestion and nutrition, and by a careful application of the fine process of Epps's Cocoa, Mr. Epps has provided our breakfast tables with a delicately-flavoured beverage which may save us many heavy doctor's bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up, and that the most delicate and nervous systems may be restored to their normal condition. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood, and a properly-nourished frame."—*Civil Service Gazette*.
Made simply with boiling water or milk. Sold only in packets, labelled, JAMES EPPS AND CO., HOMEOPATHIC CHEMISTS, London.
Makers of Epps's Chocolate Syrup for Afternoon use.

HOLLOWAY'S OINTMENT and PILLS.—Whenever the weather is variable and the temperature constantly changing, the weak and delicate must be very careful to neglect no symptom of disordered action or ill-health. Weakness and straggling subjects find in these pills the means of casting out the bad humours which originate and prolong their sufferings. The Ointment should be well rubbed twice a day over the chest, and taken in conjunction with the pills. It will penetrate and act most wholesomely and energetically on the diseased structure. These remedies manifest a wonderful power in removing all morbid matter from the blood, and consequently in curing a multitude of chronic ailments, which seemed to be almost irremediable.

THURSDAY NEXT, MARCH 23.

MASDEVALLIA CHIMÆRA, RCHB. F.

DISCOVERED BY M. ROEHL.

The true species, with its flowers 2 feet in diameter. Much has been written about this species, and various kinds have been sold for it, but excepting the few plants sold by us in 1880, none have been imported. M. Roehl discovered it in 1871, and he tried for years to get it home alive, but without success. His nephews also failed, although for some eight years they sent it home, or came home with it, almost annually. We are extremely pleased at being able to offer now a very splendid lot brought home by Mr. Chesterton, and the importation is in splendid health, the majority of the plants being very grand. The flower-spike is from 1 to 2 feet long, and the immense flowers are produced in succession, as many as seven and eight open one after the other, the diameter between the tail ends being 2 feet, each sepal being 1 foot long. The marking of the flowers varies from rose to crimson, on a yellow hairy ground. Several of our 1880 importation have flowered, and proved this to be the finest of the section. It was figured in the *Gardeners' Chronicle*, July 23, 1881. The plants have the upright spikes on them.

MASDEVALLIA REICHENBACHIANA, ENDRES.

We are extremely pleased at being able to offer, for the first time, this truly superb new species. It is, without doubt exceedingly lovely. Professor Dr. Reichenbach says:—"The beautiful plant was discovered in Costa Rica, by my late friend Endres, and was named by him." The flowers are large, fully 2 inches in diameter, the tails very short, and the colour of the flower is white, the inner half blood-red, in some varieties crimson. The distinct two colours (white and red), the striking flowers, and its fine, full, open shape, make it one of the showiest of Masdevallias, and we most earnestly commend it to the special notice of growers. We may also mention that only a few plants of it existed in Costa Rica, and that Mr. F. C. Lehmann has sent home to us every plant that could be found. The consignment is in really grand condition.

ODONTOGLOSSUM VEXILLARIUM | **DENDROBIUM WARDIANUM.**

Klaboch's autumn-flowering variety.

A specially large and fine consignment.

CATTLEYA DAVIANA.

CATTLEYA CITRINA.

ROYAL NORFOLK SEED ESTABLISHMENT,
NORWICH.**

ASPARAGUS PLUMOSUS.

An elegant evergreen climber, from South Africa, with slender smooth stems, and numerous spreading branches; the hermaphrodite white flowers are produced from the tips of the branchlets. It is an exceedingly handsome ornamental Plant for the Greenhouse or Conservatory, and its pretty feathery growths are extremely useful for cutting for Decoration. *ros. 6d., 15s., and 1 guinea.*

ASPARAGUS PLUMOSUS NANUS.

An exceedingly graceful evergreen Plant, very useful for all kinds of decorations, and from its exquisite beauty, particularly well adapted for furnishing cut sprays for intermingling with flowers; it is also charmingly elegant when grown in pots as a Table-plant. Mr. W. B. having imported a large quantity from South Africa, is enabled to offer good plants at *ros. 6d., 15s., and 1 guinea.*

ASPARAGUS VIRGATUS.

This remarkably elegant feathery-looking Plant, of fountain habit, has been recently introduced from the Cape of Good Hope. The stems, which issue from the crown of the stout fleshy roots, are of a dark green colour, and bear at the upper end a corymbose head of erect branches, of which the lowest is the youngest and most recently developed. These branches are again twice branched, the ultimate branchlets being furnished with acicular clubmolds, $\frac{1}{2}$ inch long, which grow usually in threes. The berries are round, about as large as an early home Pear. *ros. 6d. and 10s. 6d.*

NEW PLANTS for 1882.

MR. WILLIAM BULL

Will send out for the first time next month the following

NEW PLANTS:

- ACMENA OVATA.
 - ACHMEA PANICULIGERA.
 - AGLOMERA PICTUM GRACILE.
 - AINSLIA APTERA.

NEW FUCHSIAS,

To be sent out the Third Week in April.

MR. WILLIAM BULL

Has much pleasure in announcing the following magnificent collection of new Fuchsias; it includes the handsome varieties from the celebrated raisers, Mr. Bland and Mr. Eckford, from whom Mr. W. B. has purchased the stocks:—

- EXPANSION—A very distinct and pretty variety; tube and sepals bright rose, the sepals completely reflexed; light bluish-purple corolla so widely expanded as to become almost flat; quite unique in form. *ros. 6d.*
- GENERAL—A fine showy flower with very large reflexed sepals of a deep rose colour, and large expanded double corolla of a rich violet colour flaked with rose. *ros. 6d.*
- GERALD—A very fine flower with rich crimson tube and sepals, the latter completely reflexed; large expanded corolla of a rich purple colour, richly striped and flaked with pink; tube and sepals of a bright rosy-carmine colour, the latter elegantly recurved. *ros. 6d.*
- MAVRELLIOUS—Tube and sepals deep rose, the sepals oval in shape and reflexed; full, double, bright blue corolla, of pretty rosette-like form. *ros. 6d.*
- MATCHLESS—A magnificent flower of good substance and excellent shape; tube and sepals deep crimson, the latter broad and elegantly reflexed; large thick well-formed corolla of a rich purple colour, striped and flaked with rose; an extremely attractive variety. *ros. 6d.*
- MINSTREL—Tube and sepals richly rosy-crimson, short tube and broad recurved sepals; corolla very full and double, ivory-white, striped with rose at the base. *ros. 6d.*
- MONUMENT—An effective double-flowered variety, with full corolla of a deep purple colour, striped with rosy-carmine; tube and sepals rosy-crimson, the latter horizontally reflexed. *ros. 6d.*
- STARTLER—Tube and reflexed sepals of a deep crimson colour; large, double, broadly-expanded corolla of a rich purple colour; striped and flaked with rosy-carmine; very effective. *ros. 6d.*
- TULIP—Crimson tube and sepals, the latter completely reflexed; very large and much expanded fully-expanded corolla of a rich purple colour; a remarkably fine flower of good substance. *ros. 6d.*

SUTTONS'

SPECIAL GOLD MEDAL,

MELBOURNE, 1880-81.

PRIZE GRASS SEEDS,

FOR
LAWNS, TENNIS GROUNDS,
AND
CROQUET and CRICKET GROUNDS,
Have been used with the greatest success in the grounds of
The Principal International Exhibitions,
ALSO IN
The Principal Cricket and Croquet Grounds,
The Principal Parks, &c.,
IN EUROPE.

"Melbourn 95, October 25, 1880."
"Sir,—By direction of the Commissioners for the Melbourne International Exhibition I have to request that you will be so good as to convey their best thanks to Messrs. Sutton & Sons of Reading, for their valuable Lawn Grass Seeds planted in the grounds of the Exhibition during the late winter. The seeds have germinated freely, and the lawns are now in splendid condition. Messrs. Sutton & Sons may accept my assurance that the introduction of their Lawn Grass Seeds into this country has been attended with very great success.—I have the honour to be, Sir, your most obedient servant,
(Signed) "GEORGE C. LEVEY, Secretary,
To the CHIEF CLERK, Melbourne International Exhibition Office, London."

PRICES:—
SUTTONS' MIXTURE for LAWNS and CROQUET GROUNDS: 3s. 3d. per gallon; 25s. per bush.
SUTTONS' MIXTURE for LAWN TENNIS GROUNDS and BOWLING GREENS, 3s. per gallon; 25s. 6d. per bushel.
SUTTONS' MIXTURE for CRICKET GROUNDS, 2s. 9d. per gallon; 20s. per bushel.

HOW TO MAKE and IMPROVE LAWNS, see Suttons' Pamphlet, New and Enlarged Edition, gratis and post-free on application.

SUTTONS' CHOICE FLOWER SEEDS, FREE BY POST OR RAIL.

SUTTONS' NEW PRIMULA—"RUBY KING."
"Deep blood red; perfectly distinct."
First-class Certificate, Royal Horticultural Soc., Jan. 14, 1879.
Price, 5s. per Packet, post-free.
Full particulars may be had, gratis and post-free, on application.

TRAVELS OF PLANTS.

SO far as the plant world is concerned man inherited a defective world, which in many regions was a desert ill provided with useful plants. The indigenous fruits of Australia were small, and its earliest population fed on Fern and other roots. The fruits of Europe before the period of the Romans were inferior Apples, Pears, Plums, and Raspberries, with Blackberries, Beech-mast, and Hazel-nuts. The ancient Britons must have fared much like the people of Arcadia—

"Acorn-meals chaff called they from the sheds
Of forest Oaks; and in their wintry month
The wild wood-whorle with its purple fruit
Fed them, larger then, and more amply poured.
And many a boon beside, now long extinct,
The fresh formed earth her hapless offspring dealt."

The existing vegetation of Europe appears to have been derived from the North by means of natural migration, or the scattering of seeds each year further afield. Wide gaps may now divide the sites of the original vegetation. There is an Oak (*Quercus cerris*), growing generally in Asia Minor, which is found in Europe only in a few widely separated stations, such as the Apennines, parts of Sicily, and on the banks of the Loire. The Pinus excelsa is another tree without a link between its stations, which are now as wide apart as the Himalayas and the mountains of Roumelia.

The continuity of the ancient forests has been destroyed by changes in the surface. There is a shallow sea now between the forests of Scotland and those of Norway, and between the Oak and Beech woods of Denmark and those of our shores; and the sunken forests round our coast, especially on the coast of Norfolk, are the remains of the chain of vegetation which at one time was stretched between England and the Continent. At the dawn of the present stage of creation Northern Europe appears to have been denuded of its vegetation by glaciers. Earlier floras had been already buried beneath many and many a layer; a more recent one was now destroyed or driven into alpine heights.

In consequence of such catastrophes as that of the Ice Period Europe became bare of plants at a time when Asia was a garden, and accordingly we may believe that long before the dawn of history plants were moving westward and southward to occupy Europe, just as population did at a later period. The origin of the most useful plants is legendary, as might have been expected. The Vine, a migratory twiner—which has run round the globe, climbed high in man's affections, and made surprising inroads on his pocket—has several disputed birthplaces. According to the legends, Africa owed it to Osiris, and Europe to Bacchus. The Jews claimed it for the slopes of Hebron. Its real birthplace was, perhaps, that same Persian paradise which produced the Fig, Peach, and Apricot. The Orange, which was unknown to the ancients, was not the "golden fruit" planted by the poets in the garden of the Hesperides, but a Chinese fruit, introduced into the West by the Arabians.

The "golden fruit" referred to is believed to have been the Citron.

These are a few of the most essential or interesting plants which several of the leading nations possessed in a period too dim to admit of its obscurity being penetrated. Barley has been traced to Tartary, and Wheat to the banks of the Indus; and here the learned have lost sight of these important cereals, and have taken up their pens for discussion with such rage as detectives feel when baffled. The Greeks were by no means incunous about plants, and in hunting down the Olive to its original site they came to the conclusion that it must have been created by Minerva and brought to Greece by Hercules. But for the destruction of the Alexandrian Library we might know more of the origin of useful plants: we must be content to utilise such knowledge as we do possess. The Crocus first sprung amid the grass on Mount Ida at the instant of an embrace between Juno and her wandering husband, greeting her there unexpectedly. As a very widespread plant it must have afterwards sprung up in many other places—perhaps on similar occasions.

Having lingered rather long in the fields of conjecture let us now push on into those of history. The most useful plants were distributed by colonists and conquerors. Tyre was an emporium from which the Apples which the Romans found in Britain may have been introduced by the Phœnicians, who came to Cornwall for tin, and who carried the Mulberry to the western shores of the Mediterranean, and planted Carthage, a city famed for farming beyond all other places of antiquity.

After the destruction of Tyre by Alexander plants continued to be distributed chiefly by the hands of soldiers. Rice accompanied Alexander from Persia, and followed the Moors to Spain, *en route*, it may be said, for America.

Cotton has a long history, and has travelled far. Alexander the Great observed it in the Punjab previous to its cultivation in Egypt, where Herodotus found linen cloth in universal use; but in the time of Pliny, Egypt, like India, was clad in cotton. This "tree wool," as the astonished Germans named it, found a congenial home afterwards in America, whence it revisits its native country in the form of fabrics from the mills of Lancashire. Rome in her day became the rendezvous of plants, which she collected with great assiduity. Italy had been bare of native fruits; Rome made her rich in subtropical productions suited to her climate, and filled her gardens with nearly all the culinary vegetables which are now in use, including that curious Cabbage, the Cauliflower, which appears to have been developed by successive steps from the cliff Cabbage, in the luxurious island of Cyprus. A Cherry tree in full fruit from Pontus entered Rome at the triumph of Lucullus. All the fruits of Persian paradises which had not been already introduced into the basin of the Mediterranean by the Greeks, reached Rome direct from their native places. The Fig, it will be remembered, had sheltered the wolf which suckled the founder of the city. It is a fruit which is said to have rendered Bacchus copulent, and which reached the neighbourhood of Olympus early.

The vegetable acquisitions of the Romans were distributed among her colonies. The Plane reached the tomb of Diomedes in Apulia "to the East," according to Pliny and thence spread over Greece and Italy, arrived in Sicily, and was in Gaul A.D. 70, the people being taxed at that time for planting it. The Cherry was in England within five years of the annexation. The Box, the Peach, the Walnut, the Vine, and the Poplar followed, as did the Pear, Mulberry, Fig, Damson, and Medlar. The Roman generals and governors in England were both anxious and able to surround their handsome villas with the trees and shrubs of Italy. The Bay or

Laurel of the ancients came with other sweet-smelling plants, which the Romans held in great favour. Our common Laurel is a *Cerasus* or Cherry, a native of Trebizond and the shores of the Black Sea, and was introduced from Civita Vecchia A.D. 1614, or about 1600 years later than the nobler shrub. The old English Elm is not a native, like the Wych Elm, and in all probability we owe it to the Romans.

It has been said that Barley was introduced into Germany and Britain by Cæsar; but in that case those countries were far behind their neighbours who possessed Barley as early as the Stone Age. *Beer*, the Saxon name for Barley, is the root of the word beer, a beverage, and here, a coarse kind of Barley grown in Scotland. The hardier kinds of this hardy cereal have reached nearer the poles, and have ascended higher up the sides of mountains than any of the other grain-bearing grasses, succeeding wherever there is a mean temperature of 48° during ninety days of the year. In Lapland, at 66° N. lat., where it cannot be sown until June, it has just sun and time enough for ripening, and none to spare; while in England our two-rowed Barley—the parent of the Barley family—enjoys a career of five or six months from the day of sowing to the day of ripening, and, having acquired a certain habit as to the pace at which it proceeds between seed-time and harvest, it suffers a good deal in hot summers, when hurried by the effects of the unusual warmth.

The Moors succeeded the Romans as carriers of plants westwards, and Spain owes them that very useful Persian forage plant, *Alfafa* or Lucern. The Olive, which yields the cream and butter of Spain, had arrived previously. At the commencement of the Dark Ages, when the North enchained Southern Europe, plants ceased to travel. Afterwards we hear of Charlemagne's garden on the banks of the Rhine, and a little later the monks became cultivators and the Crusader's brought agricultural information from the East. But the circumstances of the age were against the travels of plants until the close of the Middle Ages and the epoch of Elizabeth. Then the Rose beds which the wars of the rival houses had trampled under foot were replanted. As early, however, as 1453, when the Eastern Roman Empire fell, "Dutch bulbs" were first grown in Holland. The Ranunculus, Anemone, Tulip, Hyacinth, and Narcissus, were all originally oriental, and were first brought from Persia to the west shores of Europe in the bales of Dutch traders. Dutch gardening was afterwards introduced here and Dutch bulbs brightened English parterres at Nonsuch, Hampton Court, Hatfield, and other places. There is a long list of ornamental trees and other plants which arrived here at the commencement of the age of industry after the close of the Middle Ages. Hops at length (A.D. 1523) followed Barley, which in the light and bitter beer of Burton they have now almost superseded. Fulham became famous for its foreign foliage, as it is still, under the auspices of Bishop Grindal. Cecil, Bacon, Gerard the herbalist, and Raleigh, all aided the travels of plants, and the latter, imitating Hercules, brought home some exceedingly useful seeds, or tubers, in his pocket, on returning from his travels. *H. E.*

(To be continued.)

LACHENALIA NELSON.—It will be in the remembrance of many that this new variety received a First-class Certificate from the Royal Horticultural Society two years or so ago; it is now in nice bloom at Chiswick, and is remarkable for the prevailing hue of orange in the flowers; it at once strikes the eye among other plants, and is a set-off against the gaudy hues of Tulips, Hyacinths, Cinerarias, &c. It is not at all unusual to meet with *Lachenalia* in pots in gardens, showing that gardeners are fully alive to their value as easily cultivated winter and spring flowering plants, and they possess a decorative value that makes them doubly useful.

BULBOPHYLLUM MANDIBULARE, n. sp.*

This is a very curious plant, quite delightful for a real orchidist. For those who prefer that name, it may be called *Sarcopodium*. If we search for affinities it might rank best near to *Bulbophyllum lasianthum* of Lindley, though it has decidedly *Sarcopodium*-like flowers, and such peculiar arms to the column, that thirty years ago one would have regarded it as the type of a glorious new genus. It was discovered in Northern Borneo by Mr. Burbidge, and has now flowered, the specimen at hand being kindly sent by Mr. Harry Veitch.

It has a glaucous bulb, over 2 inches long, much compressed, pear-shaped. The large leaf is cuneate oblong acute, a span high, 3–4 inches broad. The fine slender-stalked raceme surpasses a little the leaf; the bracts are concave, triangular, not quite equalling the ovary. The flowers are a little longer, though not so wide as those of *Lycaste tetragona*. The sepals and petals are brown, washed with light green. There is a white area at the base. The lip is straw-coloured, with purple, and with purple prickles. The column is whitish, purple at the base, and with similar spots above. It is a very curious thing, though nothing in the eyes of lovers of grand beauties. *H. G. Rehb. f.*

DENDROBIUM NOBILE (Lindl.) VAR. NOBILIUS, n. var.

A grand variety! The sepals and petals of these giant flowers are of the most resplendent purple, and the lip is darker and finer in its mottlings than any I have ever seen before. It came from Sir Trevor Lawrence, who fully appreciates his curiosity, and who kindly states that the bulbs are exactly those of the common *Dendrobium nobile*. What a pity!

Something nearly like it, but much smaller in dimensions, was sent me by Mr. William Lee, of Leatherhead, but I had no indication about the appearance of the bulbs, hence I do not feel quite sure about it. *H. G. Rehb. f.*

[This most lovely *Dendrobium* came originally from Rollisson's, at whose sale it was bought by Mr. James, of Lower Norwood, an ardent and intelligent lover of Orchids. He has with long care and persistence (for the plant was nearly dead when sold), raised a small stock, of which he lately had only one left. The variety leaves all *D. nobile*, even the darkest, far behind. *T. L.*]

MASDEVALLIA SHUTTEWORTHII XANTHOCORYS, n. var.

A lovely variety of this well-known species, with a nearly yellow odd sepal, finely striped with brown lines. The spots on the side sepals are flat, less numerous, and the whole flower is thinner. I have to thank for this Sir Trevor Lawrence, M.P., Bart., who is always bringing out some curious novelty. *H. G. Rehb. f.*

THE DATE PALM.

In my garden at Mentone I have planted many Date Palms (*Phoenix dactylifera*) which flourish all along the Genoese Riviera in the more sheltered regions. They are thriving but developing slowly, except in two instances, which throw a light on the peculiarities of the tree. On one terrace there is a row of Palms planted twelve years ago, all healthy, but small. One of these Palms is an exception to the rule. It is six times larger than the others—2 metres

* *Bulbophyllum mandibulare*, n. sp.—Pseudobulbo compresso pyriformi plano; folio cuneato oblongo acuto stipitato; racemo foliis subseguente gracili paucifloro, glanduloso; bracteis concavis ovatis acutis ovum pedicellatum non omnino sequantibus; floribus magnis illis *Lycaste* tetragone æqualibus, minus albis, carnosulis; meo obtuso; sepalis ligulatis acutis dorso carinatis; tepalis subrotundis acutis breviter lobatis; labello carnoso cordato triangulo medio late impresso sulcato; extrorsum utrinque hispido muculato muculis brevibus; columna prorsum brachium anclitibus ligulatis curvatis supreme muculatis.—In Borneo insula detex. cl. Burbidge. Col. cl. Veitch. *H. G. Rehb. f.*

25 centimetres (7 feet) in circumference, whilst the rest, planted at the same time, are only 75 centimetres 1 foot from the ground. It is quite a tree, and bears yearly fruit that ripens, some of the other Palms being male plants and flowering at the same time. I was long unable to explain why this one Palm should have developed in so rapid and extraordinary a manner as compared with its companions, but one fine day the mystery was solved. Twelve feet below the terrace on which the Palm grows, on the other side of a thick masonry wall, is a conservatory in which there is a water-tank. On cleaning it out a mass of Palm roots were found at the bottom. They had descended to the bottom of the terrace, passed underneath the masonry wall, and had reached the water. Thus the axiom of the Arabs was literally accomplished—for a Palm to flourish, its roots must be in the water and its head in the flames.

In another part of the garden the same lesson is taught in another manner. One of my neighbours had a right of way through my property, and the water passed over a terrace which had been carefully trenched to the rock to a depth of about 5 feet. On this terrace are planted various Palms, and the water passed once a week during the summer in the immediate vicinity of a *Livistona australis*, a *Chamærops australis*, a *Latania borbonica*, and a *Cycas revoluta*. The recently trenched ground let the water soak in like a sponge, and the four plants named have grown so rapidly that they are now five times the size of all the others in the terrace. My neighbour came to me a year or two ago, and with tears in his eyes accused my plants of drinking up half his water on its weekly passage. In the face of their preposterously rapid growth I could not deny the imputation, so I made him a channel outside the property into which the water was diverted. I thus also got rid of his right of presence on his water days.

The entire mountain district in which my property is situated owes its vegetation to a spring that rises in a neighbouring ravine about as thick as one's arm. In winter, by immemorial prescription, this spring belongs to three mills for crushing Olives. From June 1 until September 15 it is owned in hours each week by the peasant proprietors; each property, or proprietor, has so many hours a week, which he can, if he wishes, sell independently of the land, or retain, selling the land. This water is valued at 1000 fr. (£40) the hour. I have bought four hours and a-half for 4500 fr. (£180), which enables me to cultivate and water my garden in summer. Without it I should be all but reduced to Cactaceæ. We build reservoirs in which to store this water, and what rain-water we can divert or seize hold of. I have a dozen, large and small. These reservoirs we can generally fill in spring with the rain-water, thus preparing for the season of drought. My reservoirs hold about 300 cubic metres of water. My water rights bring in about the same quantity, so that I have in all 600 cubic metres or yards of water wherewith to irrigate during the usual four or five months' drought, viz., from May to October. Thus, we have to husband the water most carefully, and principally succeed with plants that grow naturally in regions where there are long droughts, such as Mexico, Peru, Chili, the Cape of Good Hope, Australia, &c.

To return to the Date Palms. They do not thrive in regions where they cannot reach water by means of their long strong roots, or where they cannot be watered. The largest Palm forest I have ever seen is at Elche, in the province of Murcia, in Spain. It is many miles in circumference, in a moist arid, burnt up spot, but then a small river runs through it; round every tree there is a large saucer or depression, and at intervals throughout the summer the river is turned into these saucers by irrigation canals throughout its entire extent. The trees are grown for profit. They produce ripe edible fruit, which are sold in all the markets of this part of Spain as an important article of food. The Dates, however, are not the saccharine Dates we see and eat in the North as a sweetmeat, but a farinaceous dry Date which grinds into flour, and is consumed as such. I was told in Algiers that they cultivate in the desert oases sixty different kinds of Date. I saw very few Date trees in the vicinity of Algiers and along the coast. They are principally cultivated on the southern side of the Mount Atlas, in the numerous oases that are found in the desert within a short distance from the southern basis of the Atlas range.

The existence of these desert oases is easily accounted for. An immense quantity of rain falls in

Algeria every winter on the Atlas Mountains, the prevalent winds being north-east or north-west, that is, moist sea winds. Immense masses of water thus fall down the southern slopes of the Atlas, mostly calcareous, and reach the sandy desert at their base. Sinking into the sand they form regular rivers underground, running along the base of the mountains from west to east, or east to west, at a variable depth, according to the amount of earth or of granitic sand that covers the calcareous rocks. Every now and then these subterranean streams come near the surface, forming a marsh or "shott," as it is called, or a fertile oasis if a spring rises to the surface, or even if the water can be tapped by wells. It is in these regions that the Date Palm grows and flourishes by tens of thousands, forming the principal food staple. If the roots reach the water all is well, as with my Palms; if not, and water can be got from deep wells, the Arabs accept the necessary labour and water them.

It is a remarkable fact that most of these marshes and oases springs are strongly impregnated with salt, which seems to suit the tree. The native Arabs get accustomed to these salt waters and thrive on them, but it is a great difficulty with Europeans, and is one of the greatest drawbacks the French troops have to encounter in their campaigns in and occupation of the desert oases. The young Date trees can be planted in soil the water of which is so greatly impregnated with salt as to be undrinkable even by the natives, and that without suffering in the least. They can, it is said, flourish in water containing as much salt as a drachm to a pint. These deep waters are easily reached by artesian wells, which the French are introducing all over the region of the oases at the base of the Mount Atlas range or within moderate proximity.

No other fruit tree thrives, nor do vegetables thrive, in these saline soils, and the wanted fertility of the oases, except in the case of the Date Palm, is a fable; moreover, in Southern regions, singularly enough, deep shade, such as that given by groves of Palm trees, all but destroys vegetation underneath. Light does not seem to penetrate under shade as in the North, deep shade all but killing ground vegetation: I see this exemplified in my garden. To give partial shade to a patch of artificial grass on a terrace I formed a canopy with a very vigorous *Buddleia madagascariensis*.

I have been obliged to thin it out, for the grass would not grow underneath as it would have done in England. This fact is general, I believe, in the South of France and in all countries where the sun is ardent and the air dry. Light is broken and more diffused in northern regions with a cloudy sky.

Date Palms seem to thrive best in sandy, granitic, schistic soils, but in the proximity of calcareous rocks or disintegrated calcareous soils, at least it has so seemed to me. The sands of the oases of Sahara lie on calcareous rocks, and are watered by rain falling on calcareous mountains. At Bordighera, on the Riviera coast, where these Palms grow in great luxuriance, the soil is principally sand, brought down by the Roya river from granitic mountains, but this sand lies on calcareous rock. In my garden the soil is entirely calcareous, but with plenty of water, as I have said, Palms grow rapidly. The deduction from the above facts is that lime and salt might be advantageously introduced in the artificial cultivation of the Date Palm, and perhaps of other Palms, and that in their period of summer growth they cannot have too much water.

In conclusion, I would add that I have at home at Weybridge a dozen Palms—*Phoenix dactylifera*, *Phoenix palmato*, *Chamærops humilis*, and *Livistona australis*—which I imported from Algerian years ago, and which have ever since then passed the four summer months in the garden, plunged in the soil. They are planted in the long cylindrical pots I introduced some years ago (30 inches deep), now known as Palm-pots. They are at present fine large plants, and pass the winter in an unused washhouse through which passes a brick flue from a stove. The temperature has generally been between 40° and 50° Fahr. In summer we water them freely, and they are very ornamental in my garden. I put them out June 1, and take them in October 1. My gardener generally gets the prize for Palms when he exhibits in the local flower shows in competition with regularly stove-grown Palms, and my example proves that the hardy Palms might be much more utilised out-of-doors in summer than they usually are. The position of my Weybridge garden is by no means exceptional. We

are very liable to late frosts in spring and to early frosts in winter. But a few degrees of frost does not inconvenience the Date Palm in the least. He has to bear it wherever he grows. According to Canon Tristram (*The Sahara*) hoar frosts are frequently seen at sunrise in the oases of the desert during the winter. *Henry Bennet, M.P., Mentone, March 7.*

COOMBE BANK, SEVENOAKS.

THIS charming country seat, the residence of V. Spottiswoode, Esq., President of the Royal Society, is situated about half way between Westerham and Sevenoaks, Kent, in a district which for picturesque-ness is not surpassed in the whole county. There are five entrances to the estate, all of which intersect the grounds at different parts where the park scenery is most beautiful, but the drive from Sevenoaks is the principal one and brings the visitor to the east or carriage front, from which there is a magnificent prospect. The mansion stands on a commanding site and is a substantial oblong block in the Elizabethan style with four towers projecting slightly from two sides of the building. Early Roses and other flowering and ornamental creepers are successfully grown upon the walls. The house and grounds are lighted with the electric light, which has a grand effect, especially in the vicinity of the lake on the north side of the mansion and upon the south side upon the margin of a steep slope clad with various kinds of trees and underwood overlooking the Warren Park, a sweeping valley surrounded by wooded elevations of considerable height. At night the beauty of the scene is very great, but only those who have been through the grounds and understand their formation can form any idea of the rich diversities which they present of rocks and rugged slopes, of fine trees, of masses of low evergreens, of velvet lawns, of valleys fertile and verdant, watered by the river Darent, which flows along the Westerham valley and through the south side of the park. Within the mansion the electric wires appear to the naked eye no larger than threads. They are run round the principal rooms under the ceiling, and the little Swan lamps are suspended from them by other wires of the same thickness about 2 feet in length. The lamps can, of course, be increased or diminished at pleasure. The small wires are also conveyed to the chandeliers and the lamps fixed to them in any numbers that may be desired. Outside the mansion a large electric lamp is fixed to each corner of the building, the whole arrangement giving the most complete satisfaction.

The terrace walk upon the south side is over a quarter of a mile in length, having fine rows of Beech upon either side, and the slope facing the park thickly planted with evergreens, among which there is a splendid row of evergreen Oaks peeping above them. The villages of Chislehurst and Ide Hill are noticeable objects from here, and the north park is rendered interesting by its view of Knockholt Beeches and the rising hills beyond. There are two noble Celars at the north-west corner of the mansion. The west front is strikingly attractive, being bounded with fine trees, including handsome specimens of English Yews upon the south, which convey the eye westward to Brasted church—a conspicuous object from the steps of this side of the mansion. The spire of Sunridge church towering above the adjacent woods is also visible from the south-east corner. A large Cedar of Lebanon at the west-end of the terrace is said to be the largest in England, and is surrounded by a distant ring of large Beeches beautifully feathered to the ground.

Upon the south-west side of the terrace are the sandstone rocks, one of the greatest attractions of the place. These caves, which are scooped out of the greensand rock, are said to have been a hiding place for smugglers in days gone by, but whether this be so or not certain it is that they are none the less interesting to the visitor. Hardy Ferns and other suitable plants are grouped in front of the caves, and there are also one or two mineral springs oozing from the rocks, which is a further attraction. The gardens are upon the east side of the house, and the woodland walks are very prettily laid out, and bordered in many cases with *St. John's Wort*. Perhaps the most charming spot is that in front of the Fern and Camellia house, where there are several beds of a rustic character, and the Warren Park, previously alluded to, sweeping away to the river Darent. There are fine specimens

of Ferns and Camellias in the fernery, comprising Cibotium regale, Dicksonia antarctica and squarrosa, and Alsophila excelsa. The plants are well grown specimens of their respective kinds. Before reaching the walled-in garden I noticed a good orchard of healthy young fruit trees, which bear good crops of fruit.

The kitchen garden, a rhomboid or square slightly squeezed out of shape, is in three divisions, enclosed within brick walls. The walls of the first division are stocked with an assortment of choice hardy fruits, and the second division is arranged in the same way, except the south wall, which is covered in with glass. A new range for growing a succession of Peaches, Strawberries, and other fruits, as well as plants for various purposes, either for the flower-garden or for producing cut flowers, of which large quantities are required at all seasons. The south wall of the third division is covered with two ranges of vinerias and a plant-house. The show-house is gay with splendidly grown specimens of Azaleas, and several fine Orchids, including Dendrobium Wardianum, Statiche profusa, and flowering Begonias in variety. The Vines are worthy of the fine houses in which they are grown and of the grower, upon whom their condition reflects the utmost credit. They are fruitful and vigorous, and promise to bear heavy crops as they annually do.

There is a range of small forcing-houses in four divisions, well appointed in every respect, in which Cucumbers, Melons, Strawberries, and plants are forced with success—early Strawberries being a grand crop. Flowering plants of Azaleas, Hyacinths, Deutzias, Eriostemons, Kennedys, &c., are kept in a cool-house, and specimen stove and greenhouse plants are grown in several other structures of the usual type, such as Allamandas, Clerodendrons, Stephanotis floribunda, Pancratium caribæum, Ficusæ, Ixoras, Dipladenias, Anthuriums, and many others. Mr. Bolton is a successful plant and fruit exhibitor, and an enthusiast as well. Every department of the garden is in high cultural order, giving evidence of a liberal employer and discreet management upon the part of those who are responsible for results.

Reporter.

NOTES FROM DUBLIN.

GLASNEVIN.—Few gardens can compare favourably with this: the advantages of its natural formation, with its gently undulating surface, its river alongside and its great wealth of fine old trees, renders it at all seasons an interesting and beautiful place; its natural advantages are also much aided by the care and skill which Mr. Moore bestows on it: everything is neat and tidy, the subjects well arranged and properly labelled with the least obtrusive label. In the houses the different varieties of Hakea, Grevillea and Banksia are so very beautiful and attractive as to cause one to regret the decline of these always lovely plants in public estimation—several fine specimens, particularly of Hakea Victoriae and Banksia speciosa with its singular bottle-brush-like formations scattered among the branches, being quite studies, an immense plant of that most beautiful of all weeping plants, Grevillea Manglesi being equally lovely. The next great feature in the great tropical houses are Brownea grandiceps (20 feet), covered with bloom; and an equally large specimen of Brownea ariza, more beautiful still, and bearing innumerable large heads of orange-scarlet flowers. It is pleasant to note that here the Bromeliaceous plants are being worked up; even now a large collection is classified, and at some future time an immense and full collection may be expected. The class sadly wants taking up. The immense plants of Palms and Tree Ferns, frequently noted before, are clean and vigorous as usual. The house containing the species of Rhododendron and the immense collection of Ericas and New Holland plants is a sight to remember. The Filmy Fern-house is at present a wilderness of fresh green seaweed-like foliage. These things are grown quite without heat, as they always must be to keep them good. The numerous collections of Orchids contain many rare plants, all in good condition, and a fair percentage in flower—among an immense bank of them arranged with pretty foliage plants we may enumerate a few of the more striking:—Cymbidium Lowianum, Cypripedium Dayanum, C. Veitchii, C. Hookeri, C. Argus, C. Lawrenceanum, Uropidium Lindleyi, Lycaste fulvescens, L. Skinneri, L. Lawrenceana, L. cruenta; Vandas, many, including Vanda gigantea; Cattleya

Trianae, Dendrochilum glumaceum, D. filiforme, Dendrobium Wardianum, D. leucoleum, Phalenopsis Schillerianum (a fine variety), Oncidium leucochilum, Angreum eburneum, and many more. The Sarracenia, Nepenthes, Droseras, Disas, are fine as ever, and the immense plant of Darlingtonia bears pitchers over 2 feet in height. The whole of the garden is interesting, and when viewed as I saw it under a bright sun and with a healthy breeze it is a treat indeed.

TRINITY COLLEGE BOTANICAL GARDENS.—The whole of the outdoor part of these gardens is devoted to hardy herbaceous, alpine and bulbous plants and shrubs, and nothing could exceed their beauty at this season. Here for the first time in my life did I fully realise the meaning of a permanent hardy plant garden. No other class of plants could possibly give such brilliant flushes of colour in the present, nor promise a greater display for the future than these. Let us note a few of the objects which form the most telling points. Here and there great patches of Anemones many feet across, bright and clean, gracefully nodding their heads in the gentle breeze, the most brilliant and precocious of them being *A. fulgens*, which here bears flowers often 4 inches across, and of an intense glowing scarlet unknown in any other flower. Then great patches of all the varieties of *Aubrietia* placed side by side for comparison, for Mr. Burbidge, although a true artist in the arrangement of his plants never loses sight of the botanical requirements of the place.

Frequently on rock and in border we come across great patches of the varieties of *Saxifraga oppositifolia* generally planted together, the light and dark rose varieties being prettily intermingled with the pure white one, each clump bearing thousands of flowers. These masses while growing in a natural manner beat any outrageous carpet bed for neatness, and their untrained beauty even when not in flower far exceeds anything that the toilsome labour of the shearing gardener can produce. *Orobus verna* is lovely here, and *Rhododendrons præcox* and *barbatum* very showy, particularly in the distance when the eye has to range over huge masses of *Aralias* white as snow, various coloured *Crocuses*, and large patches of the different *Scillas*. *Anemone penina* is pretty everywhere, but it appears to greatest advantage growing naturally on the turf. This arrangement of plants is much studied here and its effect is exceedingly good, everywhere in the grassy glades a few artistically placed flowers greatly enhance the beauty of the scene.

But amid the maze of beauties one gets lost; let us therefore only just notice the wonderful collection of *Narcissi*. All the sorts in cultivation are here, and many of them by the thousand. *Daffodils* everywhere—in the grass, in the wild garden, and properly classified, in the trim, but to me melancholy-looking botanical ground. The *Hellebores* are also here represented by a full collection. They are now in great beauty, and are in themselves well worth going to see. I thought I knew *Helleborus foetidus*, but when I saw it with over 400 flowers I doubted it. The *Hollies* and weird-looking *Arbutus* are wonderful, many of the specimens being 30 feet high, and nearly as much across, fresh and shining. We must not omit to notice the edgings of the borders and the cappings of the walls, which are being made very neat by using up spare stonework to form seats and low rock for the reception of suitable close-growing plants. In this way the only really pretty edging I have ever seen is produced, and in several places the irregular, verdure-clad tops of the walls altogether changes and extends the scene, forcibly reminding me that Mr. Burbidge, the designer, is an artist as well as a plantsman.

Hastening by the rockery and pond let us notice a few of the good things under glass here; in spite of the old-fashioned and often inconvenient construction of the houses, everything seems flourishing and going on instead of back. Among the Orchids at present here are in bloom or bud a fine plant of the true old *Cattleya Warscewiczii* delicata, *Cattleya labiata*, several fine plants; *Dendrochilum glumaceum* and *D. filiforme*, every one's pet; *Cypripedium Dominianum*, C. Boxalli, C. villosum, C. javanicum, C. niveum, C. Harrisianum, C. pardinum, several *Lycaste* Skinneri, *Cymbidium Lowianum*, *Odontoglossum* and *Masdevallias*, some fine varieties of *Coleogyne cristata*, *Angreum eburneum*, several *Dendrobes*, the most noticeable of which was a grand variety of *D. primulinum giganteum*. Here also in the warmer house we find the rare *Phalenopsis*

violacea and an immense plant of the old form of *Phalenopsis grandiflora*, with leaves over a foot in length, and large many-branched spikes. As a single specimen this now rare variety is far superior to those of recent importation; it grows three times the size of the other, and is easily distinguished by its long unequally lobed pointed leaves.

In the greenhouses, among a number of wonderful things we find fine plants of the rare *Nantheorhiza hastilis* and *quadrangularis*. The warm houses are skilfully arranged with Fitcher-plants, Ferns, Palms, and other fine-foliage plants, the edges of many of the stages having *Panicum*, *Tradescantia*, *Fitonias*, and mosses creeping over them, while the walls are mostly covered naturally with *Maidenhair*, which greatly improves the appearance of the houses, and helps to keep a healthy moisture in them. The filmy Ferns here are grand—as in most places in Ireland—and the *Droseras* and *Disas* equally good. Altogether Mr. Burbidge must be complimented on the success which has attended his efforts to produce lovely hardy flowers, effectively arranged without their botanical interest or use being in the least interfered with, and finely-grown plants in houses of that comfortable temperature which makes a visit to them so pleasant.

MOUNT MERRION.—Always fresh and fair with great beauty of its own, and a grand panorama of beautiful views of sea, mountains, and city, is now in fine order. I found Mr. Welch with his children, the Orchids, and very pleasantly they seemed to be looking at him too. The whole collection is in fine condition, some few things being extraordinarily fine—*one plant of Lælia superbiens* with a spike to feet long, bearing thirteen large flowers, being worth a long journey to see. *Cypripedium villosum aurum* is also very distinct, and quite the best variety of C. villosum; C. Boxalli, a grand variety, with fine black-spotted dorsal sepal. *Mesospindium sanguineum* is here represented by a splendid variety, which makes it a very desirable plant. The air of Dublin seems to be very beneficial to Orchids; wherever you see them they are healthy and without disease.

MOUNT ANNVILLE.—Here the principal features are the wonderful natural fernery, rockery, and cascade under glass (in this place any lover of Ferns could spend a whole day), the Orchids, and the immense collection of fine-foliage plants and Ferns. In the extensive houses here it would not be difficult to pick out enough large specimens to furnish forth the whole display at a large flower show; how such an immense collection gets the care and attention it most certainly must have with an ordinary garden staff is beyond my comprehension. The only thing that will account for it is that Mr. Fisher must be a clever organiser of the labour at his command. Amongst a general collection of well grown Orchids a good feature is a houseful of fine plants of *Vandas*, most of them in flower—their beauty must surely pointing to the fact that their star will again be in the ascendant shortly. The conservatory is the gayest I have ever seen at this season, flowers being exhibited as thickly as possible in cleverly arranged groups among Ferns and fine foliage plants. *James O'Brien*.

SPRING FLOWERING DECIDUOUS TREES.—Of all the useful subjects that are either in flower or coming into bloom just now, two stand out distinctly as having conspicuous merits. These are the Cherry Plum, known as the *Pyrus myrobalana*, and the well known Almond. Both are most profuse of bloom this season, and this is their general characteristic. The former is found here and there only, possibly because its fruit is of inferior quality, though useful for tart making and other purposes. At Chiswick and other places, good sized standard trees are in full bloom, a considerable way ahead of other Plums in this respect. The branches are literally sheets of white blossom for their full length. It deserves a prominent place in every shrubby border, though it is seldom met with. Being of vigorous growth, it should, when planted, be allowed ample space in which to develop itself. The Almond tree is more generally grown, and it is this season most prodigal of its blossoms. Whenever it is to be met with, thick clusters of its pretty pink flowers, that cover the branches from base to tip, give it an appearance most welcome at this season of the year. The colour of the flowers is in marked contrast to the snowy whiteness of the Cherry Plum, but both are extremely attractive.

Orchid Notes and Gleanings.

CELOGYNE MASSANGANA.—The illustration of this fine plant, which accompanies the present number, was taken recently in Mr. B. S. Williams' nursery at Holloway. The colour of the flowers varies under different conditions—the specimen figured and described in the *Orchid Album*, t. 29, having a deeper yellow tint in the flower-segments than others that we have seen, and in which the colour was creamy-yellow, with the lip light brown or ash coloured, with yellow stripes, and edged with white. The plant is a native of Assam, and was named in honour of Mons. D. Massange, of Baillonville, in whose collection it first flowered (see *Gard. Chron.* 1878, x. 684). It is a free-growing plant, of

to those in his own establishment; he is, in consequence, able to select for illustration the finest and most distinct varieties, and those most remarkable for rarity or other characteristics. The technical descriptions by Mr. Moore are in English, Mr. Williams himself supplying the cultural notes. Incidental notes relating to remarkable Orchids, or to noteworthy collections, are also given, which add to the interest of the book. The particular plants illustrated will be catalogued under the head of Plant Portraits.

DENDROBIUMS ON BARE BLOCKS.—There are some very fine plants of *D. Pierardi* growing in Messrs. Veitch's nursery on this system, and a wonderfully fine plant of *D. noble* hangs in a pan, from which the roots cannot now derive any sustenance, so that it also may be practically termed a block plant. There is also an immense specimen of *Ceologyne cristata* at present in flower at Messrs. Veitch's, but what is most remarkable in this plant is that one bulb

FIG. 54.—DENDROBIUM FORMOSUM GIGANTEUM.

easy cultivation, requiring plenty of light, shading from the burning sun, and plenty of moisture, especially in the growing season.

PHAIUS GRANDIFOLIUS.—I saw a fine specimen of this lovely old Orchid in bloom the other day at Nonsuch Park, Cheam. It had five spikes produced from one bulb, the tallest measuring about 5 feet, and the others nearly so. Standing as it did on a centre stage reaching the roof, it looked grand indeed. G. K.

THE "ORCHID ALBUM."—We have several numbers of Mr. B. S. Williams' *Orchid Album* now before us. The illustrations are noteworthy, not only for their faithfulness, but from the care which has been taken to select fine varieties, such as Mr. Williams' variety of *Laelia purpurata*, Mr. Day's *Phalenopsis amabilis*, *Cattleya guttata* Leopoldi, *Dendrobium Ainsworthii roseum*, *Laelia xanthina*, *Cattleya velutina*, and many others. Mr. Williams has access to many of the finest collections in the country in addition

has thrown up two fine spikes. Has this occurred before?

DENDROBIUM FORMOSUM GIGANTEUM.—Orchid growers who have once seen this fine variety are sure to wish to add it to their collections. It is a variety of *D. formosum*, and like it, has pendulous spindle-shaped pseudobulbs, with racemes of very large white flowers, with the lip blotched with orange-yellow. The plant flowers in early summer, and lasts several weeks in flower, having, in addition to its beauty, the additional charm of sweet fragrance. The plant is a native of the eastern Himalayas.

CATTELYA TRIANE YAKS.—Amongst numerous fine forms of *Cattleya Triane* in the Messrs. Veitch's nursery, *C. Triane formosa* may be described as the finest. The sepals and petals are pure white, with just the faintest suffusion of pink. The centre of the lip is yellow, the margin broad and well defined, of a pale lilacy-purple colour.

COLONIAL NOTES.

A COCOA-NUT GROVE IN QUEENSLAND.—On the Pioneer River, exactly opposite to the town of Mackay, is to be seen one of the most remarkable sights in all Australia, the Cocoa-nut groves of Mr. Barnes. It is some sixteen years since Mr. Barnes conceived the idea of growing Cocoa-nuts, and he selected his present homestead with that particular view, and it appears to be eminently suitable for the purpose. The land is a low-lying sandy and vegetable deposit, at one time covered with Mangrove trees, and just about on a level with high spring-tide mark. In fact, dams are made in places in order to keep back these tide waters.

Mr. Barnes has a grove of 1200 of these beautiful trees now healthily growing upon 10 acres of land. The oldest planted are perhaps some 20 feet in height, but the majority are not yet up to that. The age at which these trees commence to bear fruit varies much, some beginning at four years old, and some not for some eight years later. When once they commence fruiting they continue without intermission—that is, a flower-stem shoots out from the base of every leaf as it is formed, so that fruit in all stages, from the flower to ripeness, will be upon the one tree at the same time. The fruit of the Cocoa-nut improves with the age of the tree, and these at Mackay are not yet up to their best, therefore Mr. Barnes has not as yet troubled about looking for an export market. The Kanakas on the various plantations buy a large number, so that it pays the proprietor better to sell, say, one-half the produce at a retail price, and let the other half waste, than to hunt for a distant wholesale buyer. For the same reason he has not commenced to dry the fruit, or express the oil, or utilise the fibre. Thus any selector thinking to go in for Cocoa-nut growing will see that it is entirely owing to the circumstance of Mr. Barnes being so close to a large town that the industry has been made to pay.

In these gardens there are many other trees as well, the most noticeable being Date Palms, of which there are 300 planted. These grow quite as well as the Cocoa-nuts, and are equally handsome. Between 300 and 400 Orange trees also are planted cut, most of which are in full bearing; some of these were evidently suffering from dryness or poverty of the soil, and a great many were injured from having been planted too near the Date trees, which rival the Bamboo in the way in which their roots ramify and rob the moisture from every neighbouring plant or tree. Many Bananas and Pine-apples are grown, and Mr. Barnes adopts the safe plan of frequently changing the ground upon which he grows these, and also plants them wide distances apart. Melons in great quantities are also grown, and are ripe in early September. As this is a full month sooner than they appear in the Brisbane market, doubtless a trade will some day be carried on in the way of the North exporting them to the South. *Queenslander.*

ADELPHI. *January 19.*—We have to contend with a very dry summer. Since the beginning of October only about 1 inch of rain has fallen. Yesterday (January 18) the heat rose to 112° in the shade, and 180° in the sun. The latter is the highest without exception hitherto recorded, and exceeded anything yet experienced. During the previous winter, in August, the thermometer registered between 2° and 3° below freezing point, which sufficed to kill or injure many of our tropical plants out-of-doors. The garden is now suffering much, and the effects of the heat, especially on European forest trees, alpine and other tender plants, is disheartening. The leaves of the Poplars, Ash, Willows, &c., are burnt as if a fire had run over them. *R. Schomburgk, Botanic Garden, Adelaide.*

FRUIT NOTES.

Apple Sturmer Pippin.—Now, when dessert fruits are scarce, I find this Apple most acceptable at the table, for it is a great favourite with every one who tastes it. The Ribston Pippin is its parent, so that one is not surprised at its excellent flavour. There are two great mistakes often made respecting it—first, the fruit should never be gathered till the middle or end of October, and it ought to be stored away in a very cool and somewhat damp place, where it will keep fresh and plump till May, or even June. The tree is hardy, and a good bearer. *J. East, Eridge Castle.*

Florists' Flowers.

NEW ABUTILONS.—The group of new varieties from Mr. J. George, which was exhibited at the meeting of the Royal Horticultural Society on Tuesday last, marks a decided advance in point of colour. The hue of fiery orange, which has been deepening towards red of late, has now assumed that colour in the later productions; and the Floral Committee wisely ratified the advance by giving to the best of the reds—*La Grande*—a First-class Certificate of Merit. This has very large and well formed flowers of a decided pale-red tint, is good in habit and bloom, and remarkably free. Whether this result came from starving the plant or not remains to be seen, but it was a great point in its favour. It did appear as vigorous as any of the others, but it was characterised by a more marked freedom of bloom. The deepest coloured red was *Dazzle*, of a very bright dark red, the flowers of fine form; *Lustrous*, bright red, the flowers of good globular shape; and *Splendour*, bright red, also of good shape. These red-flowered varieties are scarcely distinct enough to be included in one batch, though they do differ in small degrees in shape and colour. Criterion, maroon-red, deep in colour, is quite distinct and good, but inferior to *Emperor*, which is in the same way, but deeper in colour, and very large and striking. *Cloth of Gold*, also awarded a First-class Certificate of Merit, is the best yellow yet seen, the colour clear pale gold, and the flowers of fine form. The colour appears at its best and in its most striking aspect when the flowers are sufficiently raised to admit of the eye fastening on the interior of the blossoms. *Orange Gem* is of a decided orange-red hue, but with the blossoms expanding too much to give them a symmetrical appearance. Of pink shades, *Enchantress*, pale rose-pink, is very attractive in colour; and *Mrs. Garfield*, silvery-pink, has very large expanding flowers, not unlike the shape taken by some of the *Fuchsias* with large mauve corollas. The *Bride* has pretty blush-pink flowers, of a very pleasing character.

It is as summer bedding and as autumn and winter flowering plants for a warm greenhouse, that the *Abutilon* is most useful. Young plants grown on during the summer months answer best for the latter purpose. They want to be on a raised stage, near the glass, in a warm and slightly moist house. This is how Mr. Barron treats his plants at Chiswick, and with so much success. Mr. George appears to have hit upon a compact-growing section of *Abutilons*, and quite miniature plants bore several flowers. Whether this strain will prove useful or not remains to be seen, but a compact habit of growth is not always an improvement, unless the plants are required to fulfil some special purpose.

CYCLAMENS.—Never before perhaps has such a fine batch of *Cyclamen persicum* been submitted to public view as that Mr. Henry Little staged at the Royal Horticultural Society's meeting on the 14th inst. There were about 200 plants, generally of large size, finely grown, splendidly flowered, and with scarcely an inferior form among them. They were all selected seedling plants, blooming the second year, and not only was there a decided preponderance of crimson and purple shades, but the blossoms of these were very fine, indeed they rivalled in size and symmetry the finest of the large-flowered section. No doubt it is comparatively easy—given the necessary skill and knowledge of the plant to grow them in a satisfactory manner—to bloom a batch of seedling plants, but the skill of the cultivator is brought into play when the bulbs or corms have to break into growth for the second year's flowering. It is then that great care is required, and success is to a large extent a matter of care and attention. Mr. Little's plants had all the vigour of seedlings combined with the highest quality of flower. *Crimson Gem*, awarded a First-class Certificate of Merit, has very large and handsome clear crimson flowers, of great size and fine form. This bids fair to make a rare parent for crossing and seedling purposes. *White Gem* is unquestionably the finest white yet raised; the flowers of great size and of singular purity, as well as being very symmetrical. This also was awarded a First-class Certificate of Merit. *Pink Queen*, like the two foregoing, belongs

to the large-flowered section, but obtained a Second-class Certificate only—an award which is of very questionable value. The flowers are of a pretty pale rose colour, and they are produced with great freedom. A variety named *Striata* is of a very novel character, the flowers having a pale rose-lilac ground distinctly striped with white. This variety may, perhaps, be made the progenitor of a distinctly striped section, but it will need to be isolated, the *Cyclamen* being so prolific of pollen that a slight shaking will distribute it. It is of a versatile character in consequence; and though a variety may be carefully fertilised with its own pollen, it will in many instances produce a varied progeny. The *Cyclamen* is being improved with such great rapidity that it is hazardous to predict its future, or limit the extent of its improvement.

CINERARIAS AT REDDEES.—Mr. James' superb strain of *Cinerarias* at Isleworth is now making a brave show, and tells far more forcibly than words can how truly strains can differ. At one time a private grower writes in ecstatic language of the grand lot of flowers he has from seed, and then another writes deploring the loose-petalled starchy flowers which it is his misfortune to possess, and protests that only named flowers are worth growing. Now the remarkable feature of the *Reddees* flowers is the very fine quality seen throughout; there is not a thin flower amongst them, but in every case the petals are stout and broad, overlapping each other, and with that singular regularity which marks now any first-class strain. A box of gathered blooms all showing this notable peculiarity naturally leads to the suspicion that they have been specially dressed for the occasion. A single glance at the fine heads of bloom in the houses at *Reddees* will suffice to show that, so far from being an artificially produced feature, it is but the product of good culture applied to a fine strain. In all directions we see flowers that are absolutely perfection in form and in colour showing some novel and most brilliant hues. Self largely predominate, the most striking perhaps being a rich mazarine-blue, with a red tinge at the base of each petal—really a grand trust of bloom. Other striking hues allied to superb quality are crimson-maroon, crimson-magenta, bright magenta, rosy-cerise, violet-blue, deep purple, and many other tints, whilst there are numerous bicolors, of which fine forms are found in *Sarah Winter* and *Master Colvin*, both very large flowered kinds, having broad belts of heavy red hues. None of the plants are now grown as specimens, but all are in 48's, thus giving room for a large variety. If all *Cineraria* strains were as fine as Mr. James' there would be no room for complaint, but probably it is because this one and some few others stand out so markedly in their quality that private growers of inferior strains find cause for dissatisfaction.

ANEMONES.—The double form of *Anemone stellata* is a poor thing compared with the broad-petalled and large-flowered single and semi-double forms of *fulgens*. I have them all here in a lump, and they are doubtless the produce of a batch of seedlings, the variations in form and shade of colour being considerable. Growing here on a warm south border that is fully exposed to the sun now, and in a hot position during the summer, the plants began to throw up bloom early in November, have continued blooming all through the winter, and for the past month have been glorious. A lady who called in the other day exclaimed, "Oh, dear, this reminds me of Nice!" and doubtless it did. But I think position has much to do with this early and abundant bloom, for I have heard complaints from several amateur gardeners, whose roots had been planted in cooler or moister situations, that they could not get bloom, or but very little. Perhaps enough account has not been made of the fact that this *Anemone* is a native of a very warm clime, and strong sunshine is necessary to ripen the roots, and fully mature them for free blooming. I know that last summer mine, in the long spell of heat and drought we then experienced, were nearly roasted, but they have never bloomed so superbly as this season. Exposure to really strong sunshine for several hours, however, has its disadvantages when the blooms are at their best, as it causes them to expand to an extent that is almost ungainly. The richest tints are seen in flowers that are about half open, and always on broad-petalled ones. The more the petals are narrowed and increased the paler the colour. No doubt the diurnal opening and closing of the blooms has much to do with their comparative endurance; but once the blooms are cut the motion ceases,

and the flowers remain expanded. In vases mixed with other white flowers and green foliage the scarlet *Anemone* is singularly attractive; but, praise and extol *Anemone fulgens* as much as you may, literally the queen of the *Anemone* family is found in the beautiful garden varieties of *Anemone coronaria*, for not only are these more enduring, often from established clumps blooming for six months, and even longer, but the deep hues and many varied colours found in a good strain allied to the stout massive petals and good form renders these *Anemones* immensely attractive. I have a scarlet so brilliant that before it fulgens literally pales its inefficent fires; and blues, purples, reds, whites, and mottled flowers in great variety give in a mass a brilliant display such as may well rival the *Tulip*. Then all the *coronaria* family are hardy and not difficult to please in the matter of culture, though well repaying for extra care and attention. But they are any one's flower to raise from seed and increase enormously. Last spring I saved seed from a few good coloured blooms, and as soon as I had got all that was wanted, and it was thoroughly ripened, I sowed in a broad shallow box in fine sandy soil, and stood the box in a frame, shading somewhat till the seed had fully germinated, which it did in a week or two. In the month of August these seedlings were dibbled out singly into a bed to the number of nearly 2000, and I believe the major portion of them will bloom at once. Next year, given double the room they now have, they will make a mass of bloom that will be really magnificent. No other hardy plant can give such good results in such a short time, for these *Anemones* are not only for to-day, but literally for years hence. I fear we have not made much progress in the production of the single and semi-double forms for forty years, since they were grown to a degree of excellence not since seen. The really double forms of *coronaria*, of which there are many named sorts, are indeed beautiful; literally the colours are gorgeous. I am growing some of these in pots this year for the first time, and hope to get a superb show of flowers presently. If some few enthusiastic florists would but take up the culture, improvement, and exhibition of the *Anemone* they would soon work wonders in helping to beautify our gardens.

A. D.

PLANT PORTRAITS.

CANNA IRIDIIFLORA EHEMANNI, *Garden*, January 21.—A noble variety, with groups of pendulous crimson flowers, each 3 inches or more in length.

CATTLEYA ATKEA, *Garden*, Feb. 4, 1882.—A very beautiful *Cattleya*, nearly allied to *C. Dowiana*, a native of Costa Rica, while this is from New Grenada.

DRACENA FRAGRANS VAR. MASSANGANA, *Bot.*, Hort. 1881, t. xvii.—Leaves elliptical, acute, shortly stalked, shining green, with a yellow centre. MM. Jacob-Makoy, Liege.

LONICERA ALBERTI, Regel, *Gartenflora*, t. 1065.—A very pretty dwarf glabrous shrub, with spreading branches and small, nearly sessile, linear oblong, sparingly toothed leaves. Flowers rosy, in pairs, with long slender corolla-tubes and spreading 5-lobed limb nearly an inch across. Native of Eastern Turkey. It is likely to make an attractive hardy shrub.

LYCOPodium DICHTOMIUM, Swarz, *Gartenflora*, t. 1067.—A species with rather thick, fleshy, forking stems; leaves in many rows, linear, spreading. West Indies.

MAXILLARIA HYACINTHINA, Kchb. fil, *Gartenflora*, t. 1066.—A native of Caracacs, with sulcate pseudobulbs, ovate-oblong leaves tapering at the base, and spikes of medium-sized white flowers springing from the base, of no special value as an ornamental plant.

MODIOLA GERANIODES, *Garden*, January 28.—A pretty *Malvaceae* annual, with deeply-cut palmate leaves, with linear toothed segments and rosy-lilac flowers nearly 2 inches across.

PARNASSIA NUBICOLA, Wallich, *Bot. Mag.*, t. 6009.—Leaves spatulate, stalked; flowers on long stalks, greenish-white, with the structure of the European Grass of Parnassus. Himalaya. Hort. Kew.

PITCAIRNIA ALTA, Hasskarl, *Bot. Mag.*, t. 6066.—A handsome West Indian Bromeliad, with loose tufted strap-shaped recurved leaves, glabrous above, white-keeled beneath; flowers elongated, scarlet, in loose panicles. Hort. Pall. It is the *P. ramosa* of Koch, but not of Jacquin. Hort. Kew.

The Kitchen Garden.

As a consequence of the unusually mild winter—if the term be applicable to the weather which we have experienced during the last three or four months—the supply of Broccoli is good and plentiful—especially good at the present time being Cooling's Matchless, Backhouse's Winter White, and Dilcock's Bride. Following these are Richmond Late White, Frogmore Protecting, Chappell's Cream, Carter's Champion, and Cattell's Eclipse—all sterling varieties. Seeds of Conner's Colossal Asparagus should now be sown in drills 2 inches deep and 12 inches apart, in a border where the soil is of a light, rich, and sandy nature, for transplanting the following year. Seakale seeds should also be sown, either in a nursery bed, in drills 2 inches deep and 1 foot between, in patches (about three seeds in each patch, which subsequently should be thinned out to one), 6 inches apart in the row, or else in the situation in which the plants are ultimately to be forced, in rows 2 feet apart and 18 inches in the rows, in light rich soil, from 2 to 3 feet deep. Plantations may also be made from cuttings of the roots, which if cut into lengths of about 4 inches and placed in a box, intermixed with sand, as recommended in our Calendar for October 29, last volume, should be dibbled in from 10 to 12 inches apart and 18 inches between the rows. These thongs, or root cuttings, will furnish plants to be taken up for forcing next November; but if they are intended to be forced in their permanent situation by the aid of pots, dung, and leaves, then the distance should be as recommended above—2 feet between the rows and 18 inches from plant to plant, and the thongs should be set about an inch under the surface of the soil. A sowing of Chervil should now be made in shallow drills; also another breadth of Turnips, Radishes, and All the Year Round Cabbage, and Victoria Cabbage Lettuce; also of the Paris Green Cos, and Paris White Cos varieties. A small sowing of each should be made at short intervals, so as always to have a good supply of young plants wherewith to make frequent plantings in order to maintain a good succession. Make another sowing of Peas every fortnight for the next three or four months of such varieties as Carter's Stratagem, Carter's Telephone, Culverwell's Telegraph and Ne Plus Ultra; also Seville Longpod and Taylor's Broad Windsor Beans; and Spinach in sufficient quantity to meet the demand for the same at the proper time.

FORCING DEPARTMENT: TOMATO PLANTS.—These, whether they are growing in pots, or planted out and trained like Melons to a trellis under the roof of the structure which they occupy, will now—especially in the latter case—require frequent attention in the way of pinching out lateral growths and thinning the leaves, as anything like over-crowding of the shoots and leaves would be prejudicial to success in Tomato culture. The application of water to the roots must be guided by the space allotted to the latter, together with the condition of the plants and the weather; and no stimulants should be applied until the plants have set their fruit, when they should be thinned out—leaving, of course, all the best-shaped and most even-sized fruits. When the plants are in flower a drier and more airy atmosphere should be maintained. Plants which are intended for fruit in pots, and to yield a supply of ripe fruit by the middle of May, should now be ready for shifting into 12-inch pots, which should be amply drained by placing a large piece of crock over the hole in the bottom of the pots, then a couple of inches deep of three smaller-sized ones, filling in the chinks on the top with the smallest, and over them a few handfuls of half-rotted leaves. Thus drained there need be no apprehension of the pots getting water-logged, or the plants when established suffering from being over-watered. The plants should be thoroughly watered the evening before being shifted into the larger pots, after which they will not require being watered until the roots have pushed into the new soil; the latter should on this occasion consist of three parts of good loam and lime-rubble (about one-third of the latter

and one of well-rotted manure. A stiff stick, between 5 and 6 feet long, should then be put to each plant, and the latter secured to it; and if the plants are stood together in single rows, on raised stages, in the forcing-houses to fruit, as is the case here, the sticks which are supporting the individual plants should be braced together by tying a few long ones longitudinally to the upright sticks at about 3 feet from the surface of the pots, which will keep the plants in position when laden with fruit. All lateral growths should be pinched back to within one joint of the main stem, and in other respects treated as recommended in the case of those planted out; and as soon as the pots become filled with roots, and the fruit set, liberal and frequent supplies of liquid manure in a diluted state should be given to the roots. Let the temperature at night range from 55° to 60°, and by day 65° to 70°, running up to 80° with sun.

POTATOS.—Successional pits of Potatoes should be earthed up, and with those in a more advanced stage of growth, together with Carrots and Radishes, watered when the soil becomes moderately dry. *H. W. Ward, Longford Castle, Wilts.*

Peaches and Nectarines.

ALTHOUGH we still have very mild weather, we have had but very little sun during the past few weeks—only now and then having a bright sunny day until the last three days, which have been indeed beautiful. Every advantage should be taken of such favourable conditions by closing early, allowing the temperature to run up, according to the directions given in former Calendars, moistening every available surface in order to induce an early and free growth that will get thoroughly ripened early in the season. Final disbudding and heeling down in the early and second house should by this time be pretty well finished except on late varieties in the second house, of which it is desirable to have at least one tree in each house, so as not to have too many fruit ripe at once, and to prolong the season of each house. This is very essential, and doubly so where there are only two or three houses. Give good supplies of tepid water at the roots as the trees require it, never allowing them to get at all approaching dryness. Weak manure-water may be given to any weakly trees, or to any that are carrying a heavy crop of fruit. Stop any strong leaders or gross shoots that are taking the lead, in order to get an equal flow of sap. Keep a sharp look-out for red-spider, which usually makes its appearance in bright sunny weather, especially where there is any foliage near the pipes. Wash at once with a little weak Gishurst Compound, or a little soap and water, before they get thoroughly established. The trees in succession-houses (third and fourth) will now require disbudding, and the most forward shoots may be heeled down. Fly the syringe freely, and fumigate at once, if there are any signs of greenfly, which is almost inevitable where plants such as Strawberries, &c., have been introduced, and a Peach-house is generally a favourite place to bring them on where there are suitable shelves for doing so. Still keep late houses as cool as possible, only just keeping out the frost when the blooms are expanding. *J. Wallis, Keele Gardens.*

Plants and their Culture.

STOVE FINE-FOLIAGED PLANTS.—These are indispensable subjects in every collection of exotic plants; they add greatly to the general effect, the more so when flowers are somewhat scarce. Attend to the young stock now making good growth. Propagate the necessary quantity to keep up the supply required of all kinds that are used for table plants and other decorative purposes in the household. For this purpose select vigorous, clean, and well-coloured growths of Crotons; cuttings of these in themselves large enough for table plants may be struck readily in a brisk heat and close atmosphere. Large-sized cuttings should be steadied with a stick. Of *Dicranas* the tops may be cut off and struck quickly enough; the tap roots of these will also make excellent plants, taking longer of course to develop the character of the respective kinds. The old stems should also be cut in pieces and struck similar to Vine eyes where it

is desired to quickly increase any given kind. Marantas can be readily propagated by division, now being a favourable time for this operation. Do not overlook *M. tubispatha*; being a deciduous kind, it may during its dormant state be forgotten and allowed to become too dry. The *Peperomias* are very effective plants in a stove, thriving well in partial shade; for the outer edges of groups of stove plants they are very distinct. These can also be increased by division during the spring. In many stoves are to be found damp walls; these, in most cases, could be readily covered with *Ficus repens*, thus turning an unsightly object to a good account, growths of this *Ficus* being at all times valuable for decorative purposes. We have the back wall of a low lean-to stove nearly covered with seedling *Adiantums*; these give a good supply of cut fronds of not too vigorous growth.

The blinds that have been taken down during the winter should now be re-fixed. The bright sunshine now to be expected will be trying to some plants, a little shade to which will be beneficial. During the prevalence of a biting easterly wind or a frost they may with advantage be let down at night, saving firing, and aiding in keeping the necessary moisture in the house. Five degrees can often be saved by keeping the blinds down at night. Shut up early during bright sunshine, allowing the thermometer to rise for a few hours to 85° or 90°. Syringe freely, and damp down the walls and paths. The night temperature may be steadily increased.

FERNS.—Any of these not yet potted should be seen to at once, increasing the stock of those most in request either by spores or division. All the old and shabby fronds may be safely thinned to give room for the proper development of the younger ones. Where any brown-scale abounds this operation should be done all the more severely. Keep the young rhizomes of *Gleichenias* pegged closely to the soil, turning the points inwards where possible, and top-dress slightly with a little fresh soil. Some kinds can be increased easily if, instead of pegging the rhizomes into the old plant, they are secured firmly on small pots filled with peat and sand. When these are considered to be rooted into the pots sufficiently, they may be divided from the old stool and then kept in the shade for a little time. Young growths of any *Gleichenias* proceeding from the sides or terminal points of the old fronds should be regulated, to ensure their proper development. Look to all deciduous Ferns, such as *Leucostegia immersa*; several of the *Adiantums*, and some *Davallias* will now be pushing up their first fronds quickly. Do not let these Ferns be kept too much shaded by other plants or the stems of the fronds will become too much elongated, and not so well able to support the weight.

FORCING PLANTS.—Any of these that are gone out of flower should not be overlooked. *Indian Azaleas* should have their seed pods picked off, and then be induced to make an early growth. *Deutzia gracilis* will flower all the better next year, if, after their flowers are faded, they are kept growing for a time, and gradually hardened off. *Azalea mollis* should be treated likewise. Spineas past their best should also be protected for awhile. Many plants grown for forcing purposes are frequently injured for another season by being placed on one side and neglected after they are gone out of flower.

GREENHOUSE.—*Solanums* that can now be dispensed with should be cut back into the hard wood and started into fresh growth to secure an early set of berries for another autumn. Cuttings that have been struck as previously advised should be potted off and kept pinched for a while; these will make better stuff than seedling plants. Winter flowering Heaths and *Epacris* should be cut down and started into growth again in a little heat to ensure an early set for another season. *Tuberous Begonias* should not be hastened in too much heat, a Peach-house at work seems to suit them very well. Another batch of seeds should be sown of such as *Rhodanthus*, *Stocks* (ten weeks), and *Mignonette* to succeed the earlier stock. Some promising young plants of *Heliotropis* should be potted on for conservatory and indoor work. Of sweet-scented flowers this is an accepted favourite. The kind called *White Lady*, I find, is very floriferous and deliciously scented. Cuttings of *Fuchsia* struck now will give useful plants for the late summer and autumn; keep all the stock now in active growth constantly pinched if stocky plants are valued. *James Hudson, Gunnersbury House, Acton.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	Mar. 20	{ Sale of <i>Lilium auratum</i> Bulbs, at Stevens' Rooms. Spring Show at Clifton, Bristol. Folwood Horticultural Society's Show.
WEDNESDAY,	Mar. 22	{ Sale of Standard and Dwarf Roses, at Stevens' Rooms. Sale of Imported Orchids, at Stevens' Rooms.
THURSDAY,	Mar. 23	{ Rooms. Sale of Hardy Plants and Bulbs, at Stevens' Rooms.
SAFER AV,	Mar. 25	{ Rooms.

THE magnificent hybrid *Amaryllis* lately exhibited by Messrs. VITCH and others raise some important questions as to what should be considered the typical form for these grand bulbous plants. As to such matters as robust habit, number of flowers and their colour, there is not likely to be any dispute or difference of opinion. Fine foliage, robust habit, free-flowering qualities, substance of petal, variety, richness and distinctness of colouring—these are all points upon which general agreement may be anticipated. Such otherwise grand flowers as *Leopoldi* are deficient in that only two or three flowers are produced in a truss; on the other hand, many of the Continental forms, though robust and free-flowering, are condemned as not being good enough as to form.

The florist's ideal is a six-parted starlike flower with a relatively short, bold, funnel-shaped tube, and broad even segments, all alike in size and form. Some such form as this, it is obvious, is the one most likely to meet with the approval of florists. The leading principle here is easy to be ascertained—it is that which demands an approximation to geometrical regularity of form, and symmetry and equality as regards proportion. Let it be assumed that this is the principle to be acted on, then it follows it should be acted on in all its details, and stamens upturned at their points and of unequal lengths should be eschewed, and any irregularity of disposition in the matter of colour should be equally condemned.

That is one way of looking at things, but there are other things worth consideration. The form of the flower before it was altered to suit the taste of the florist is something very different. In place of symmetry and geometrical regularity, the flower in a natural state spreads horizontally from its stalk, or is even bent down upon it, and is almost two-lipped. Take the old *Amaryllis formosissima*, for instance—the flower is abruptly bent downwards upon its stalk; the three uppermost segments form one lip, as it were, placed almost vertically, the three lower ones form a lower lip placed at a different angle. Kich as the colour is of these flowers no florist would accept it as a type to be followed, neither should we do so. But we think the florist would do well to consider the probable meaning of that form. No one can look at that flower now-a-days and observe its position, the form and arrangement of its segments, the manner in which the lower ones are rolled round into a tube at the base, the varying lengths of the stamens, and their direction downwards, without being convinced that this deviation from the geometric arrangement of a six-parted, regular, star-shaped flower, has a distinct purpose, and that purpose the fertilisation of the flower by insect agency. The bright colour of the flower, and the abundance of nectar, lead to the same conclusion.

Again, the fact that the stigma is protruded beyond the anthers, and so bent away from them that access of pollen from the stamens of the same flower is rendered difficult if not impossible—a difficulty intensified by the fact that the anthers are ripe at one time, the stigma at another—renders cross-fertilisation a necessity. It is clear then that the flower is, so to speak, adapted for special purposes. Fundamentally, it is, as we have said, a geometrically regular 3-parted flower, with an outer row of three segments, and an inner row of similar segments alternat-

ing with the outer, three outer and three inner stamens, and so on. All this is no theory, it is a fact, as any one may prove for himself by examining a flower in its earliest conditions. The irregular arrangement, the unequal lengths, the varied disposition of colour, are all later developments—adaptations adapted for the benefit of the plant and its offspring.

The florist is apt to overlook all this, and to lay down an artificial standard of form to suit his particular purpose. To this proceeding on his part there can be no objection raised—he is free to do what he pleases; but as consistency to a guiding principle is, to say the least, under any circumstances, desirable—is, indeed, what he aims at—then we may point out that in reverting, as he attempts to do, to the original geometric plan upon which the flower is founded, he should endeavour to carry out the process consistently, else he is likely to produce a meaningless, expressionless flower, which is displeasing to the eye even when the spectator fails to see wherein the source of the unpleasant impression lies. To have a perfectly funnel-shaped *Amaryllis* flower, with the colour regularly disposed, in combination with stamens of unequal lengths and bent downwards, is, to our thinking, altogether false taste, for it is suggestive of something false—of something that no longer exists; it tells of an arrangement of parts and of a state of things no longer of any use—their purpose is gone, their presence in such a shape is an anachronism.

If then an *Amaryllis* is to be judged according to the ordinary standard of form regulating florists' flowers, let the thing be done thoroughly, completely, and with intelligence, else you produce a sort of mermaid or centaur, a monstrosity half one thing half another—a thing the history and meaning of which are, if not entirely destroyed, at least perverted and distorted. In illustration of our meaning we may allude to *Vallotta purpurea*, in which the flowers are erect, nearly if not quite regular, with the stamens of equal length and regularly disposed. Some such form as this, subject to any modification which the nature of the case demands, is in our judgment the standard of form in an *Amaryllis*, at least it is a consistent and intelligible one.

—PROLIFEROUS PINE.—Fine growers know the value of gills and suckers in their proper place, but they are not likely to be greatly enamoured of such a specimen as that now figured (fig. 55). Nevertheless, it is interesting as showing the essential identity of the "pips" in the ripe fruit with shoots. For some reason or other, what we know not, the flowers and fruits have not been developed, but in their place an infinitude of shoots or suckers, each one of which would serve to perpetuate the plant, and as each one would in all probability form a "fruiter" under the ordinary treatment, the peculiar appearance of the parent might be condoned. The specimen was sent to us from Arundel Castle Gardens by Mr. WILSON.

—MENTONE.—We are informed that Dr. BENNETT's garden at Mentone has been placed at HER MAJESTY'S disposal during her stay on the Riviera. We have on former occasions given illustrations of this remarkable garden on the hillsides, facing the sea, where from the hard rocky soil and the fall exposure gardening is carried on with difficulties—difficulties, however, which the enthusiasm and physiological knowledge of plants and their requirements possessed by Dr. BENNETT enable him to overcome, as is evidenced indeed in the communication from his pen that appears in the present issue. Dr. BENNETT's letters on gardening in the Riviera, and on the vegetation of that lovely region, will be remembered by many of our readers, and much of them has been incorporated in his well-known work, *Winter and Spring on the Shores of the Mediterranean*, and to which renewed attention will be attracted in consequence of HER MAJESTY'S visit. We hope shortly to publish further illustrations of Dr. BENNETT's garden.

—ACACIA VERTICILLATA.—This species was one of the very first of all the numerous Australian and Tasmanian Acacias to find its way into English gardens. According to PAXTON'S *Botanical Dictionary* it was introduced in 1780. It is a desirable plant for conservatory decoration, has whorls of Gorse-like phyllodia and stalked oblong heads of lemon-yellow flowers. Sir JOSEPH BANKS, in an article "On Inuring Tender Plants to our Climate," in the *Transactions of the Horticultural Society*, instances this as a plant which, if his suggestions were followed, might prove hardy or almost hardy in the country. In the article in question Sir JOSEPH strongly advocates the propagation by means of English-ripened seed of several successive generation of Myrtle, Cherry Laurel, Sweet Bay, and other more or less tender shrubs. In order to point his moral, that a few generations would in all probability mark a decided increase in ability to withstand frost, &c., he mentions that *Zizania aquatica*, the Canada Rice—a grass which of late has begun to attract the attention of paper-makers—after once fairly started, grew larger and stronger each successive generation until some of the plants were 6 feet high, and the whole pond in which they grew was in every part covered with them as thick as Wheat on a well managed field.

—THE ROYAL BOTANICAL SOCIETY OF BELGIUM.—The twentieth volume of the *Proceedings* of this Society contains a full list, with localities, of the plants native to the Canton de Vaud, by MM. PITTIER and DURAND, and a notice on certain old trees in Switzerland.

—DAPHNE BLAGAYANA.—For the rockwork or for pot-culture for cool-house decoration, this pretty *Daphne* (figured at p. 245 of vol. xiii.) is eminently suitable. It is a dwarf grower with large terminal clusters of pleasantly-scented, creamy-white flowers. A recent introduction (from the Carpathian Alps) to British gardens, and perfectly hardy. No plants are now in flower at Kew.

—THE FLORIST AND POMOLOGIST.—The March number contains plates of the double-flowering Wistaria, Bedford Prolific and Bigearau Gros Coeur Cherries. Mr. James continues his articles on *Cine raria* culture, while Mr. BARRON'S very useful descriptive list of Vines is brought to a conclusion; altogether ninety-four varieties are described.

—ANEMONES FROM THE SOUTH OF FRANCE.—Miss CLARA MANGLES sends us from Cannes a bouquet of Anemones, wild varieties of *A. hortensis*, very varied in form and colour, including the forms known as *A. fulgens*, intensely rich in colour, *A. pavonina*, with very double scarlet flowers, the segments linear, the inner ones tipped with white; *A. stellata*, with whitish and rose-coloured and lilac flowers; the whole forming a series ranging from white to crimson and lilac, all very bright and vivid. With them also comes a cut spray of *Bougainvillea speciosa* of a most intense purplish-lilac colour, much finer than anything seen under glass in this country.

—THE BOTANICAL MAGAZINE.—The plants figured in the March number are—t. 6611, *Catalpa Kumpferi*; t. 6612, *Masearenhaisia Curovianii*; t. 6613, *Wahlbergia saxicola*; t. 6614, *Taliuma Candollei* var. *Galeotiana*; and t. 6615, *Scutellaria Hartwegii*. Further details will be given in our Register of Plant Portraits.

—FICARIA GRANDIFLORA.—This is an extremely fine plant of its kind, and it seems to have found happy conditions in the Cambridge Botanic Garden among the bog plants, where it is growing 9 inches above the water. It is so robust as to look almost like a small *Calla*, and the golden flowers are quite 2 inches across.

—PRIMULA CARPATICA.—This rare and interesting species is now blooming in the Cambridge Botanic Garden, where it is much earlier than its immediate allies. It comes near the *Cowslip*, but is quite distinct. The present plant has a scape with ten flowers, eight of which are open. They are nearly an inch across when spread, of pale yellow colour, without an eye, and possess a somewhat remarkable perfume, which may be described as aromatic, and something like that of *Lycaste* are-

FOLIAGE
ONE HALF REAL SIZE

CELOOGYNE MASSANGIANA.

matica, though less intense. The features which now appear the most striking comparatively are the dark, stiff-looking leaves, the thick clothing of soft hairs on the scape, short pedicels, and the peculiar perfume. The first scape was produced a few weeks ago. It was contributed by Dr. KANTZ, of the Klausenburg Botanic Garden. *Primula rosea* is first in blossom in the open where sunk between four bricks to preserve

through is too generous in its profusion to suit the market grower. Abundance may mean plenty to take to market, but then it means plenty everywhere, and as a result the returns are by no means commensurate to the size of the loads sent, or to the labour involved in the gathering. When a big sack of Turnip-tops brings but a miserable sixpence it needs little arithmetical ability to deduct from that sum the cost of

Broccoli, but the heavy losses incidental to this crop during the previous three or four winters have naturally made growers chary of largely planting, so that when once the hardier greens have disappeared—and they cannot last long—we must expect a long interregnum in the spring ere Peas and Broad Beans will be ready to fill the void. Spring Cabbages are not so universally grown as could be desired. They will not thrive

FIG. 55.—A PROLIFEROUS PINE-APPLE. (SEE P. 372.)

moisture, and the protection appears to have forwarded it. In our own garden there are at present no signs of flower in this species.

— MARKET GARDENS.—Market gardeners are so busy getting in their crops, and are working under such exhilarating influences that they worry much less than might otherwise be the case over the very poor prices obtainable for green stuffs of all kinds. In truth, such a winter as that we have just passed

production and marketing, but very much indeed of knowledge to discover the profits. What holds good of Turnip-growing is relatively equally true of the bushels of sprouting Broccoli, of curled Kale, of Brussels heads, and similar members of the Brassicæ family. Not only are all these various field crops turning in all at once, but they are quite a month earlier than usual, and thus the market is being unduly forced and glutted. The most natural succession to these hardier greens would be large breadths of white

well on all soils, and too often for various seasons turn in as "bolters" rather than as good profitable heads. The chief spring green crop will be Spinach, but that, too, cannot long endure, as the advancing season will push it on rapidly also. If, however, market returns are so poor for present crops the splendid weather and the free working conditions of the soil, the enormous abundance of seed Potatoes, and the generally moderate charges for other seeds, all combine to shelter over market gardening a hopeful

aspect. Not only should such a spring-time indicate abundant crops presently, but work everywhere should become plentiful, and buyers richer than they have been of late.

—**PRUNUS DIVARICATA.**—This species, although rarely producing fruit in this country is well worth growing as an ornamental tree. It makes a nice specimen for the lawn, and its numberless snow-white blossoms, so much in advance of those of most of the other species of the genus, render it a welcome inmate of the shrubbery or park. It is a native of Eastern Europe and Western Asia, and in all probability several of our cultivated Plums derive their origin from it. A good sized tree is now in full bloom on a lawn near the Cactus-house at Kew.

—**NEW COMMERCIAL PLANTS.**—Mr. CHRISTY'S publication of this name, just issued, relates to tanning materials, and their respective values and uses, for the guide of colonists and others. Oaks, Mimosa bark, Babool, Mangrove, Quebracho, Divi-divi, Betel-nut, Myrobolans Valonia, and various other substances containing tannin, are mentioned, and the means for ascertaining the percentage of this material described.

—**SPENOGLASTRA CONFINNA.**—This beautiful little plant first flowered in this country rather more than twenty years ago in the establishment of Messrs. VEITCH. At that time it was not known who imported it, or even what country could boast of being the home of such a floral gem. The stalked leaves, borne in little rosettes, are green above, and covered with a network of deep red veins beneath; the Gloxinia-like blossoms are of large size—if one considers the stature of the pigmy plant which produces them—and of a pale lilac colour, deep blue on the upper part of the tube and throat, yellow below, the throat spotted with purple. A native of Tropical America.

—**ACER OBTUSATUM AND A. NEAPOLITANUM.**—Amongst the earliest flowering and most striking of the larger ornamental trees and shrubs are the two above named forms of the rather widely distributed and variable *A. opulifolium*. Some round-headed compact trees of these are now covered with bloom at Kew. The flowers are borne in terminal corymbs, the sepals and petals are yellow slightly tinged with green, the stamens being bright yellow. Some good spring effects could easily be produced by planting this species where it could be made to afford a pleasing contrast with the deep red-flowered *A. rubrum* and the lighter-coloured Silver Maple, *A. dasycarpum*.

—**FORESTRY.**—The College of Agriculture at Downton, near Salisbury, includes this subject in its course of tuition, as will be seen from the following extract from the prospectus:—

"*Forestry.*—The history, propagation, treatment, uses, and value of timber trees. Management and general use of underwood. The planting, thinning, and general management of Fir plantations. Measurement of standing and felled timber, and of converted timber. Use of sliding-scale. Sale of timber and underwood. The economy of woods and forests in the management of estates. The lectures are supplemented by practical classes in the neighbouring woods.

"*Mensuration and Land Surveying.*—Measurement of surfaces. Quantity of land cultivated by various implements. Areas occupied by crops. Mensuration of solids, and estimates of the contents of tanks, ditches, wells, manure-heaps, walls, ricks, stacks, timber, road metal, cuttings, and embankments.—Field and road surveying. Plotting and drawing of plans, and determination of areas surveyed. Levelling, tinning, and details of the use of prismatic compass, quadrant, &c. Details of the chain, theodolite, and levelling staff. Mode of keeping surveying and levelling books. The Ordnance Survey, Ordnance maps, and bench-marks.

—**CASSANDRA CALYCUATA.**—"The calyculated Cassandra," according to LONDON'S *Arboretum*, and "Leather-leaf," according to GRAY'S *Manual*, are the English equivalents of the by no means cumbersome botanical name of this pretty plant. The first-named one is hardly likely to be adopted even by the most rigid advocate for popular names, and the latter, to English ears at least, does not convey or suggest any definite idea of this plant in particular. *C. calyculata* is a neat-habited shrub of easy cultivation, requiring simply the treatment under which Rhodo-

dendrons and a host of other peat-loving plants flourish. Its Mossus-buds are formed during the summer and expand the following spring. At the present time its white flowers are being produced in profusion. According to LONDON this species was introduced in 1748; it is on record, however, that at that period it was cultivated by the Duke of ABERYLL, "the tree-monger," so it does not seem improbable that to that nobleman is due the credit of introducing it to this country. A native of the North Temperate Zone.

—**AMERICAN BLIGHT.**—According to the *Wiener Illustrirte Garten-Zeitung*—the organ of the Vienna Horticultural Society—the "Monatsblatt" of the *Gartenbau-Gesellschaft von Mairisch* recommends an unfailing remedy for this pest. It is simply to grow at the foot of the Apple trees the common Nasturtium or Indian Cress, *Tropaeolum majus*. Probably few cultivators in this country would possess sufficient faith in this so-called unfailing remedy as to give it a trial; still, in the case of newly-planted trees especially, it would be very easy to test its merits or demerits even in a single season. Grow Nasturtiums near one lot of trees, and keep them clear from another similar lot under the same physical conditions, and then report progress at the end of the season. In some nurseries where large numbers of Apples are annually grafted train-oil is applied with a brush to the stems wherever the "blight" puts in an appearance. In other establishments, where an equally clean-stemmed good stock is reared, a dry brush is used, or even simply the hand, to crush the insect. In the *Transactions of the Horticultural Society* Sir JOSEPH BANKS gives a series of "Notes" on the first appearance of the *Aphis lanigera*, together with various experiments on infested Apple trees. Flowers of brimstone, soft soap, &c., seem then to have been not a whit more successful than friction with the hand. A note dated January, 1794, says:—"Mr. JACKSON, who at my desire had seen Mr. DUBHUIS' gardener at Bethnal Green, above mentioned, brings word from him that when the insect first appeared in the autumn of 1789 he thought himself wholly ruined, but that now he receives very little damage by it. . . . Since that time he employs men to rub the insects with their hands between the stocks, and in this manner one man will clean a thousand grafted stocks in a day. He says that care must be taken to tread the ground close to the roots, as the greatest damage is done by these insects when by means of cracks in the earth they are enabled to fix themselves on the tops of the roots, or on the stems, where the roots are inserted."

—**GESNERA ELONGATA.**—If but a single flower or even a cluster of blossoms from this plant be compared with those of a host of others belonging to the same family, and some, indeed, belonging to the same genus, the comparison from such material could not fail to be disadvantageous to the subject of this note. When, however, its habit, and the profusion with which its scarlet flowers are produced are taken into consideration, it will be at once admitted that these characters abundantly make up for the small size of the flowers. The species makes a shrub several feet in height, and the contrast between the green leaves and the long-stalked blossoms, which are generally borne in fours, is most pleasing. A good specimen is now in bloom in No. 8 house at Kew.

—**THE COFFEE LEAF DISEASE.**—A very interesting memoir has lately been published in the *Quarterly Journal of Microscopical Science* by Mr. H. MARSHALL WARD, who was on special duty as cryptogamist to the Ceylon Government. The matter is not only of consequence to the cultivators of Coffee—as in the case of every disease it is of prime importance to ascertain the exact nature of the Cryptogam to which the disease is attributed—but because, in a scientific point of view, it modifies very materially the views which have hitherto been entertained on the subject. The parasite, when first discovered, seemed so abnormal in its structure that MESSRS. BERKELEY and PROOBE, who first described it in this journal, Nov. 6, 1880, were unable to come to any definite opinion as to its affinities; but in their memoir of the Fungi of Ceylon they placed it amongst the Uredines, and when it was stated by THURWELL that the spores when germinating gave rise to a species of *Aspergillus* the matter seemed still more perplexed. Mr. ABEAY, whose observations are pub-

lished in vol. xvii. of the *Journal of the Linnean Society*, found on the germination of the spores that they gave rise to a very remarkable species of *Penicillium*, and considered the so-called spores to be sporangia, which seemed to modify the matter still further, though we did not consider the production of sporidia, if they may be so called, within the sporangia as of material consequence, as similar conditions are sometimes produced in abnormal growths, as in the foot fungus of Madura, and indeed in the yeast fungus. Mr. WARD, however, has shown, by a very careful series of observations, that after the spores are produced another set arises, which are clearly of the same nature as the teleutospores of Uredines; that these germinate and produce conidia; and consequently that the plant really belongs to that tribe of fungi, and that the first spores are Uredo spores. On referring to Mr. ABEAY'S memoir it is clear that he had observed these teleutospores (see tab. 13, figs. 11, 12), but unfortunately he regarded them as "barren cyst-like bodies," and so by the merest chance failed in ascertaining the true affinities. It is to be observed that Mr. WARD did not see anything either of the *Aspergillus* or *Penicillium*. It appears from the account of the disease by Mr. DYER, in the twentieth volume of the same journal, that a second fungus, the *Aspergillus* or *Penicillium*, grows on distinct spots (see tab. 9, fig. 1), and that therefore it might very possibly be mixed with the *Hemelia*, so as to cause some difficulty about ascertaining the real nature of the germination. Mr. DYER, after the observations of Mr. ABEAY and Mr. MORRIS, was led to regard the spores as sporangia. We have now, therefore, at last the true history of the parasite, and are in a position to work out the remedy, or at least to work in the right direction. It is impossible to speak in too high terms of Mr. WARD'S labours. *M. J. E.*

—**COMMON LAURELS AS FLOWERING SHRUBS.**—The value of many of our common shrubs for giving ornamental effects is not so generally known as in the interests of horticulture it should be. What, for instance, can be more despised than the common Laurel? although, of course, its rare habit and rapid growth is fully recognised for various purposes of planting where other things would not survive or grow sufficiently dense and thick to answer certain purposes. But clumps of Laurels in full flower at this season are vastly more used as garden or pleasure-ground ornaments than the majority of people suppose. At Linscombe Castle, South Devon, there are clumps furnished to the ground upon slopes by one of the carriage drives which are aglow with beautiful white flowers, and have been for some weeks past. There is a dense background of green as well as a healthy green carpet beneath the clumps, which enhances their attractions and reminds one that rich effects may be produced by using very ordinary material in the way of plants. Where they are planted *en masse* in other portions of the grounds they bear a different aspect, and although gaily dressed with abundance of flowers there is a monotony about them which wearies rather than charms the eye. This is mentioned because it is the common way of planting, but it does not follow that because a plant is common a position cannot be found for it where it may look a striking ornament. Laurels have been in flower at Linscombe for several weeks past, but it should be stated that the situation is exceptionally well sheltered and the climate all that can be desired.

—**OLIVE OIL IN SICILY.**—It is stated that Olive oil produced in Sicily has very much improved of late years. The mode of preparing it has been hitherto the cause of its not attaining that delicacy of flavour possessed by oils of Italian and French manufacture. Oil in every respect equal to that produced at Lucca may now be obtained at Termini from Olives grown in the vicinity of that town at about 60s. per cwt.

—**BERBERIS DARWINII.**—Large plants from 10 to 15 feet high are now in flower in the grounds at Linscombe Castle, Dawlish, wherethey are in charming contrast to green Hollies, Portugal Laurels, and other evergreen plants. They are chiefly planted by the sides of walks and occupying conspicuous corners, where they have a most pleasing and cheerful effect—such an effect as is difficult to describe, owing to the profusion of orange-coloured flowers with which the bushes are clothed. They seem to

droop so naturally, one branch overlapping another, while in many instances a vigorous branch or two shoots out a couple of feet or more from the rest, as if Dame Nature had taken particular pains in the completion of the floral picture.

— **HYACINTHS IN HOLLAND.**—We learn that owing to the mild winter and spring, the bulbous plants in Holland are much earlier than usual. The early varieties of Hyacinth, such as Homer, Maria Cornelia, Latour d'Auvergne, are already in full bloom. By the end of the month, if the weather continue, the Hyacinths will be in full beauty, and those who defer their visit till the middle of April as usual, will be too late. The most convenient routes from London are *via* Queensborough and Flushing, or Harwich and Rotterdam. The traveller from Leyden to Haarlem may now avail himself of the steam tramway between these two towns, and which passes through the Hyacinth fields, stopping at numerous stations. Passengers by rail between these points see little of the flowers. The Crocuses are already past their best.

— **THE BERNE CONVENTION.**—The Belgian Government has announced its adhesion in principle to the modified Berne Convention of November, 1881, relating to the transit of plants, in countries where, owing to the panic concerning the Phylloxera, severe restrictions are still in force. This will allow the Belgian horticulturists to partake of certain privileges and exemptions relating to the transit of plants, and to have a voice in the matter of framing the regulations that may be necessary in future.

— **THE WEATHER.**—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending March 13, issued by the Meteorological Office, London.—The weather though generally dull during the earlier part of the period, with rain in the west and north, became very fine and dry towards its close. The temperature has been above the mean in all districts, the excess ranging from 5° in most of the western districts to as much as 7° over eastern and central England. The highest reading (64°) was registered at Collymore on the 7th, and at Nottingham on the 10th, whilst at most other stations the maxima varied between 55° and 63°. The minima occurred either on the 7th or 13th, and were rather low, ranging from 28° in "Scotland, E.," and the "Midland Counties," to 35° in "Ireland, S." Rainfall has been a little more than the mean over Scotland and in "Ireland, N.," but less elsewhere. Bright sunshine shows a slight increase in most districts the percentages varying from 17 in "England, W.," and 18 in "England, S.," to 41 in "Scotland, E.," and 36 in "Ireland, S." Depressions observed.—The barometer has been highest over France, and the extreme south of England, and lowest over Scotland and Scandinavia. Depressions travelled in a north-easterly direction across our north coasts during the greater part of the week, causing the gradients for south-westerly winds to grow steep, and the wind to increase to a fresh or moderate gale on our western and northern coasts. Towards the close of the period, however, the barometer became more uniform, and the winds light or moderate in all parts of the kingdom.

— **GARDENING APPOINTMENTS.**—Mr. W. CRUMP, for the last six years gardener to the Duke of Marlborough, Blenheim Palace, Woodstock, has sent in his resignation, and is going into business at Leamington as flower and fruit grower for market.—Mr. HENRY HATCH, late Foreman at Stanwick Gardens, near Darlington, has been engaged as Gardener and Bailiff to Colonel HOWARD VISE, The Manor Cottage, Old Windsor.—Mr. ARTHUR HOLLOWAY, late Foreman at Foxbury Gardens, Chislehurst, has been appointed (through Messrs. CHAS. LEE & SON) Gardener to R. REID, Esq., Barra Hall, Hayes, Middlesex.—Mr. R. PAGE, late Foreman to Mr. FRATT, The Gardens, Hawkstone Park, Shrewsbury, has been engaged as Gardener to C. HILL, Esq., Clevedon Hall, Somersetshire.—Mr. H. WARD, late Foreman to Mr. MUSSELL, Cadland Park, Southampton, has been appointed Gardener to Sir PHILIP EGBERTON, Oulton Park, Tarporley, Cheshire.—Mr. R. SAUNDERS, late Foreman at the Marquis of DOWNSHIRE'S, Easthamstead Park, has been engaged as Gardener by the Hon. A. G. J. PONSONEY, Heatherfield, Ascot.

FORESTRY.

HEDGES.—Next to plantations nothing so much beautifies and adorns the landscape and the country in general as hedges, and the more that agricultural improvements are advanced the more will hedges be appreciated both for beauty and utility. Any one who for the first time beholds the garden-like field formation and distribution of Thorn hedges in Roxburghshire, the Lothians, Ross-shire, and some other districts of Scotland, is alike pleased and surprised with their beauty and utility. The first consideration, after determining its purpose, in planting a hedge is what description of plants to plant so as to suit the soil, and effect the purposes of protection and afford shelter to the kind of stock upon the farm. Unless the soil is of sufficient quality to grow a good strong plant, and maintain it in health and vigorous growth in future, it is inadvisable to plant hedges upon it.

After many trials, long practice, and frequent failures, the following among other successful results have been achieved:—In planting common Whitethorn hedges the first thing to do is to trench, lime, and otherwise thoroughly prepare the ground, which should either be of a clayey or strong loamy nature. The plant bed should be about 4 feet wide by at least 2 feet deep, and the ground both underneath and on all sides well broken to a good depth, and thoroughly drained. It is advisable to have the preparation of the ground done in summer or autumn, and the planting done as early the succeeding season as possible. The plants preferred are strong seedlings (two or three years old), and should be put in without any cutting except in extreme cases where the roots are extra long and bare, in which case they should be slightly shortened with the knife. I plant nine or ten plants to the yard, and keep the hedge clean by hoeing and raking for several years thereafter, and never cut over the plants till they have made two years' growth, when, with a sharp hedge-bill, or pruning-knife, they are cut over to within three inches of the ground.

At the end of the second two years' growth they are again cut over at 18 inches from the ground, and again at two years afterwards at 3 feet from the ground; thus, at six years from the time of planting, there is a close and good hedge 3 feet high, and as they seldom require to be more than 4 to 5 feet in height altogether: this height is attained at the end of seven years, after which the hedges may be pruned either once or twice a year as circumstances suggest. One rule ought to be, never to prune the hedges at midsummer till they have attained their full desired height. No young hedges—that is, such as have not attained their full height—should be pruned in the summer season, nor till the young wood is perfectly ripe and matured, otherwise pruning stultifies and throws the hedge into a state of distorted and gnarled growth, from which it never afterwards quite recovers.

Beech hedges should be planted much in the same way as Thorn hedges are, with these differences:—The soil for Beech should be as light and dry as possible, and it thrives well in the remains of an old turf dyke which has been levelled down. It should never be pruned, except the straggling outside lower branches kept within bounds till the hedge is about as high as required, after which the top growth may be stopped and the hedge allowed to thicken at pleasure, and after it has attained its full size may (but not till then) receive a mid-summer pruning, for the sake of beauty and neatness. Beech hedges do well for affording shade and shelter, but are too soft as a protection against animals, unless grown upon the top of, or, rather, behind a wall or face dyke, where they answer remarkably well. As a roadside fence, too, they do good service, and have a nice clothed appearance both in their velvety summer green and russet winter brown.

I prefer planting hedges comparatively thick, and when they require it thin them out with a pruning knife, which is a commendable practice, as thereby the remaining plants derive more room and consequently grow stronger.

Holly hedges are both serviceable and beautiful at all seasons, but specially in winter. The ground, preparatory to planting, should be trenched to a depth of 3 feet, and about 4 feet wide, and the soil should be a sandy loam, neither too light nor too heavy, but rather heavy than light. Like the Beech,

it should not have its top shoots at all interfered with till as high as it is wished to be grown, after which the top of the hedge should be cut level and the hedge ever afterwards cut once or twice a year as taste and other circumstances recommend.

The *Prunus myrobalana* appears also to be (for it has not been long much in use) a very good hedge plant, but requires mixing either with common Thorn, Sweet Brier, or other less rapid growing species to thicken and give compactness to the hedge. This kind of hedge is planted and treated in every way the same as Thorn hedges, but the plant requires a still better soil to grow in, nor is it certain if it will grow to such old age as the Thorn even under the most favoured circumstances.

The Elder makes a useful and suitable shelter hedge for many exposed places when inferior soil and climate are also to contend with. It grows readily from cuttings, and any soil, if at all loose and deep, is suitable to it. It can be trained up to a good height, and affords excellent shelter to animals, which are by no means fond either of eating its leaves or gnawing its bark.

The Willow, of which there are many varieties, grows well almost anywhere, and will either succeed in very light dry soils or in soils of the opposite extremes. In dry soils it survives to old age, but in wet soils it rarely attains middle age. It should be constantly, that is, annually pruned, and, like the Elder, trained to a considerable height, and thereby form one of the very best screens or protection fences for sheltering Hop gardens, young plantations, paddocks for young and tender animals, &c.

The common Buckthorn (*Hippophae*) is an excellent hedge plant, and does well to mix along with Willows on tops of turf dykes, or embankments near the sea, or indeed almost anywhere and in any soil. It requires pruning annually, otherwise it grows stunted and does not spread either root or branch satisfactorily. It grows from seed and from cuttings, but best of all from layers or runners, which are easily obtained from plants growing on light soils anywhere.

Whins or Gorse also make good hedges, which succeed well on turf dykes, but in consequence of their liability to die periodically from the effects of frost and their attraction for rabbits they are less planted now than formerly. The Whin hedge is sown (rarely planted), and the common method is to make a scratch in the ground, as if for sowing Turnips, and from a bottle with a goose-quill fitted into the mouth the seed is sown and covered with a small rake or hoe. The plants come up the same season as sown, and require little further treatment beyond keeping the grass from choking them the first and second season, and annually pruning the hedge after sheeding its flowers.

It is an excellent plan to extend one or two runs of wire in both Whin and other hedges as near the top as possible, to constitute a back-bone to them, which is of the greatest importance wherever cattle are to fence against, for there are few hedges in which there are not some weak parts, and the strength of a hedge, as of a chain, is determined by its weakest part.

Mixing hedges, as Thorn and Beech, though common, is not commendable, because if the soil is adapted to Beech it outgrows and kills the Thorn, and if suitable to Thorn it grows much better without the Beech. In winter, too, a hedge composed of Beech and Thorn always presents a gappy appearance at a distance, for in spite of all efforts the one or other die out. Evergreen hedges for their own sake should be annually pruned in May, when all the old and withered foliage is pruned off, and the young shoots allowed freedom and time for completing their growth before the end of the season. There are, however, opposing considerations which have to be taken into account, such as the flowering of Whins, Rhododendrons, &c., and it is not till these and others have shed their blossoms that pruning is admissible. The beauty and neatness also which a newly pruned hedge presents at midsummer has of itself such attractions that it may be some time before Nature's laws are, in regard to pruning, fully obeyed. *C. Y. Michte, Cullen House, Cullen.*

ROSE FORTUNE'S YELLOW AT WESTONBIRT.—An extraordinary plant of this favourite Rose may now be seen in full flower in a cool-house in the gardens at Westonbirt House, the residence of R. S. Holford, Esq. Mr. Chapman, the gardener, informs me he has cut over 800 blooms this season, and the plant is now entirely covered. The value of such a plant can scarcely be over-estimated. *Tricolor.*

HOME CORRESPONDENCE.

Garden Prospects.—The winter of 1881-82 has been quite to my mind, and I am inclined to pronounce it the perfection of a winter; and if we could but foresee that in future all our winters would be like it, the "agricultural depression" would vanish, the horticultural world rejoice, because there would be no more reductions in gardens, and market growers would leap for joy, in that they were no more to be handicapped in the market by the produce of my lord duke's garden, such produce being required for home consumption. But, alas! my fickle climate has so often jilted us that all confidence that it means to permanently mend its ways is gone, and therefore, whilst hoping for the best it will be wisdom to prepare for the worst. The promise of a more fruitful season could not be possible, and our hopes having attained so high a pitch, a failure would be proportionately heavy, so that to prevent such a disaster it is worth while to take extra precautionary measures to protect tender flowers, vegetables, and especially fruit blossoms. Peaches and Apricots are now with us (Hants) in full flower, and flowers, too, the like of which, for individual vigour and profusion, we have not seen for years; their appearance is sufficient incentive to determine us to spare no pains in warding off "Jack Frost." Pears, too, are marvellously well budded, and unfortunately some are opening; those on walls are easy of protection by boughs, netting, tiffany, &c., but the low standards and pyramids are more difficult to deal with; still we don't mean to be mastered, and some—the choicer kinds, at all events—will be protected by large spray branches of Birch, Laurel, or Spruce Fir, the thick end being fastened into the soil, and the spray amongst the branches, with here and there a tie to prevent wind chafing. Plums and Cherries are also liberally covered with buds, and all that can be done to protect them should be done at once. Coming to vegetables, kitchen gardens have more the appearance they usually present at the end of April than the middle of March. Without any special attention we have never failed of a supply of Cauliflower or Broccoli since we commenced cutting the early Cauliflower at the beginning of June last, and now there is a superabundance which, for the double purpose of prolongation and protection from frost, is being lifted and heeled-in under a north wall. The less advanced is looked over for the purpose of being covered with their own leaves whenever there seems to be any likelihood of frost. The earliest Cauliflowers that are intended to succeed the late Broccoli are already planted out in deep drills; they are thus sheltered from cold winds, and little or no earthing-up is necessary other than levelling in the drills as soon as growth admits of it. Radishes, Early Horn Carrots, and the earliest open-air sowings of Cauliflowers, Broccoli, Savoy, and Cabbage receive partial protection by using the Strawberry nets or two or three ply thick. The earliest Potatoes are already peeping above the soil, and earth is drawn to and over them so long as it is practicable to do so, afterwards they are protected with long litter. Pans sown January 6 are already 4 inches high; earthing and a screen of evergreen boughs on the windward side is the best protection for these, but happy shall we be if none is required. Certainly we are not yet out of the wood, and it may be risky to proceed to get in the general stock of seeds and Potatoes; but the ground works so well, and under all conditions are so very tempting, that, risk or no risk, we mean to get them in, and by way of a change have a leisurely April. //

An Error in Exhibiting.—At the last meeting of the Royal Horticultural Society one exhibitor showed a tray of double *Cinerarias* placed on a background of vivid mauve-coloured paper. The effect on the flowers was ruinous; the blooms, although good in colour themselves, were destroyed by this flaming mauve colour: it made all the blooms look dead and livery by contrast. All brightly-coloured plants should be mounted on dull-coloured backgrounds—a dull even olive green is perhaps the best contrast. A bad fashion seems now very prevalent of dressing little girls in brilliant crimson head-dresses: the effect on the face of the child is that it makes it look like a corpse. The delicate and pure hues of a healthy face require tints of a sober nature to harmonise with them. How would a delicate flesh-coloured Tea-scented Rose look muffled round in a mass of blood-red velvet? *H. G. S.*

The Season at Edinburgh.—As instances of the very exceptional temperature of this season, I send for your use two facts which I believe are unprecedented in Edinburgh horticultural history. In the

middle of February a Carnation in a perfectly open and unprotected border had a flower perfectly expanded, and another is now fully out on the same plant. Again, in the grounds of St. Koop's villa on the south side of the city, a bush of *Camellia Stuyi*, about 4 feet high, which was put out last autumn in a perfectly open and unprotected outside border, had a flower well expanded in the beginning of the last week of February, and two others are now well expanded on the same bush. *T. Ivory, 23, Walker Street, Edinburgh.*

Nicotiana affinis.—I have a great many plants, but I cannot get any of them to bloom during the daytime. They only open in the evening, and close soon after sunrise in the morning. Mr. W. H. Cullingford tells me this is quite his experience with this plant. *T. Christy, Malvern House, Sydenham.*

Heating Experiments.—A little over a year ago, when referring to the then announced great show at Kensington, you suggested there would be a good opportunity for a boiler trial. As, however, there were no preparations made, and if there had been there was no time for it, no trial took place, though the medal awarded was for the best boiler "practically and scientifically considered." There is now a better opportunity in the forthcoming implement show, extending over six weeks, at Kensington, as there are three classes with six medals specially for heating appliances, but the judges—even if the best gardeners in the world and thoroughly competent to decide on the best flowers and fruit and general implements—may not be practically acquainted with the details of hot-water heating, or with what constitutes a perfect apparatus, without something to guide them in the way of a test. The question of glazing and ventilation, too, is one about which there may be, and always is, a great difference of opinion, and yet it is one which could be very simply tried, and observations on different days, with thermometers to show the maximum at night and minimum by day (if in sunshine all the better), so as to show the least variation in temperatures in twenty-four hours. Lawn-mowers are tested, and rightly too, while the other twelve classes are such as may be judged readily. Considering that the erection of glasshouses and the heating thereof are the preliminaries (and most expensive ones too) in our climate to the successful growth of the varied flowers and fruits, it is surprising to me that at all our great exhibitions, it is surprising to me that societies like the Royal Horticultural and other kindred ones do not test annually and publish reports on the various appliances, in the same way that they do with flowers, fruit, vegetables, and small implements, I believe. For instance, there are at Chiswick many houses and several varieties of boilers in use; it would be a simple matter to keep a record of the sizes and shapes of boilers, quantity of piping attached, with description and quantity of fuel burned, and, with either a detailed or averaged daily temperature kept up above the outer atmosphere. One or two houses or ranges, too, could be set apart specially for testing new boilers, a week at a time, during the late spring or summer months, when the pipes were not particularly wanted, so that an inventor might send (if so inclined) and fix one there himself, and by payment of a small fixed sum to cover expenses and the privilege of trial, have an unbiased report on its working and consumption of fuel, &c., which would often prevent a worthless article being offered to the public. Such a set of trial pipes might be permanently fixed at Kensington, either in the arcades or adjoining the conservatory (its pipes even might be divided and used) or near the offices and Council-room, arranged in groups or coils of 300 and 400 feet each, so that any size of boiler, from 600 to 2000 feet power, could be readily tested. Gentlemen about to commit themselves to an expenditure of £1000 or more in new gardens would willingly pay as much as £50 to have a boiler set on a system of glazing tested, and avoid the costly blunders of others they have heard of, believing that amount might often be saved to them afterwards in the cost of fuel alone. If such trials were instituted and properly carried out, we should very soon be able to arrive at some tabulated statement that would rectify the erroneous calculations founded on experiments when hot-water heating was in its infancy, and there would not be any difficulty in such a trial, as the heating power of well known London nurseries (as an instance two years ago, when certain "improved" boilers were put in, which did not heat the pipes with more than double the fuel consumed subsequently in more powerful boilers, which reduced fuel, by-the-by, is more than ought to be burned to heat the quantity of piping. In the face of such corrected tables as might be obtained of the actual working powers of boilers, manufacturers and engineers would not pollute the high heating power of that they now do, which heating engineers, though stated as "approximate," are known to be wrong; but because one or two makers will keep these figures on their lists, all the others must do likewise, or lag behind in the struggle or business; while it cannot be expected that

a gentleman or his gardener can have the special knowledge necessary to calculate for himself in the absence of any reliable rule for doing so. This leads me to the question of the judging of boilers at shows, and without wishing to be unjust in any way, or to appear too critical, I fancy it would be a strange commentary on the judgment given at some of our recent exhibitions, if the successful boilers and some of those left out in the cold could be tried together under the same conditions. Judges are but human, and, as the merits which decide them in cases of fruit and flowers, and in at least half the implement classes, appeal more directly to the eye, it will happen (perhaps unconsciously) that the mere look or finish of a boiler and its accessories, in the absence of any strongly marked points, will go a long way in influencing their awards. The position of a judge is a thankless one at the best, as I know, there being always some disappointed exhibitor who thinks his article the best; but in some classes, and especially those I refer to, the judges' duties would be lessened, and their decisions more understandable, if the points on which they were to adjudicate were made known to all alike beforehand by the committee. If times had been more prosperous, I should, ere this, have started an experimental house or two for the purpose of revising the heating-tables still referred to, the necessity for which revision is evident by a quotation from Mr. Fawkes's new book, in which he gives the formulas of Tredgold and Hood, as well as his own observations. It is necessary, says the one, to have 202 feet of pipe per cubic foot of air to obtain an internal temperature of 45° above the outside; on opposite page it says that 55 to 65 feet only of pipe are required. The two sets of figures are confusing, and on examination, the former is found to be to heat so much air per minute; but whether so much air requires to be heated per minute or per hour is not generally known or ever explained. The same writer's lectures, now publishing in the *Gardener's Magazine*, will be useful in some way, forming impressions as to how to heat, and I was preparing similar by an influential and independent body like the Royal Horticultural Society, and published in all the gardening periodicals, would educate our gardeners on subjects almost as important as the soils to use, and the treatment to be observed in the cultivation of plants. *Engineer.*

The Single Blue Roman Hyacinth.—I agree with the writer of the note at p. 36 of the *Gardener's Chronicle*, that it would be better not to call this Hyacinth Roman, but instead of that Paris or French Hyacinth, which is the true name, although French growers now offer it as Blue Roman. I doubt, however, if the Hyacinths which are said to have been sold twenty years ago in London as Belgian Hyacinths can be considered as identical with this plant, and I suppose this as well as other French Hyacinths (except the earliest white Roman) have not been known long in England. I have seen a few of them, probably the *Scilla variegata*, Hyacinth de Link (not *nutans*, Smith), of which the various forms were called in Dutch and other gardens for a long period, and even now sometimes, *Hyacinthus belgicus*, or Belgian Hyacinth. *J. H. Krelage, Haarlem.*

Cianthus magnificus.—The enclosed truss is sent to show you a rare example of the mild winter in the north of Scotland. The plant from which it is taken had been trained up the rafters of a greenhouse, and was turned out of the pot about the beginning of May last to fill up a vacant space and by the frost on the roof of my house. It has not received any protection of any kind excepting shelter from a plant of *Ceanothus aureus* growing beside it. Some of the branches are heavily loaded with flowering racemes. Previous to 1868 a plant in a similar situation lived through several winters, and flowered freely later on in the spring. It is much harder than *panicus*. *J. Webster, Gordon Castle, Tothabers.*

The Winters of 1760-61 and 1881-82.—The following may prove interesting, as it shows the mildness of the winter of the year 1760-61, which somewhat accords with that of 1881-82. "December, 1760: On the 21st a reaven's nest, with young ones just fledged, was taken from a tree in a ground belonging to Mr. Johnson, of Gedney, in Lincolnshire. "January, 1761: The season is so forward that on the 14th instant there was in Combe Wood, between Wimbledon and Streatham, in Surrey, a thrush's nest with four eggs in it, some of which were fresh. On the 21st a thrush sitting on a nest, very laid ten days before, and the hen sitting on a nest, also ten days before, and at a place near Regyate a plate of great plenty, and of such a size, as I have never seen produced a few days since at a gentleman's table. And from Swansea, in South Wales, we have the following letter, dated the 23d inst. "Last week several flocks of swallows and other summer birds were seen here, occasioned by the mildness of the season; but 'tis thought that the present Aut

(which came pretty sudden and severe) must have destroyed the greatest part of them, as many have been found frozen to death. A few days since there was a Pear tree in full blossom in a gentleman's garden not far from this town; and a Gooseberry bush which stood under a wall and was fenced from the north wind had Gooseberries as large as Cherry-stones; and 'twas thought had the mild weather continued, several sorts of summer fruit would have been ripe before Easter.' We likewise hear from Eshgill, near Alston, in Cumberland, that on Christmas day last a gentleman there had Marigolds and ten other different kinds of flowers in full bloom (the same as in the months of May and June), and all the trees in his garden in bud, owing to the mildness of the season—a circumstance never known before in the memory of man, so far north. *Annual Register*, Harrison Weir.

Primulas.—I have grown most of the leading strains of *Primula sinensis* during the last thirty years, but I consider Mr. B. S. Williams' *Alba magna* the finest white *Primula* I have yet seen. It not only produces beautiful flowers, but the habit of the plant is so good, with its rich beautifully curled foliage, not unlike the curled *Mallow* used for garnishing. Its lovely flowers are carried well up above the foliage—a habit which adds much to its beauty. I have during the present season used a different compost to any I have used previously, and with very good result. It is as follows:—One part of turfy loam, one part of turfy peat, and one part of leaf-mould, with a little charcoal and bone-dust, and a liberal quantity of Bedfordshire coarse sand. With this compost, well-drained pots, and careful watering there is little fear of damping-off at the stem. *H. Ellis, Gr. to W. Agnew, Esq., M.P., Summerhill, Pendleton.*

Tulipa chrysantha.—I have now in bloom a bulb which answers almost precisely to Mr. Baker's description of *Tulipa chrysantha*. The flower is large, pale straw-colour, with a dull orange eye, the back of the petals flushed with pink. It is a very distinct, handsome, and conspicuous species, and when more common will be a great addition to the hardy bulb garden. In habit of growth it resembles *T. altaica* and *Schrenkii*. I received the bulb without a name from my kind friend M. Max Leichlin, who told me it came to him from Bokhara. I have great hopes that it will go to seed. *H. Harpur-Creux, Drayton-Bauchamp Rectory, Tring, March 13.*

Cyclamens from Mr. H. Little and Mr. H. B. Smith, in which brilliancy of colour and general refinement of character are associated with free-flowering tendencies. The *Amaryllis* and *Abutilons*, which contri-

FIG. 58.—DISEASE OF GRASS: ISARIA FULFIFORMIS.

get away from the haphazard system heretofore prevalent. Among the Orchids grand plant of *Cymbidium album*, from Lord Rendlesham's collection, attracted much attention, being in perfect health; and bearing twenty-nine of its ivory-white flowers; and hardly less was bestowed upon Mr. J. C. Bowring's fine plant of *C. Lycaste fulvescens*, with its sheaf of bold leaves overarching a dense tuft of light olive-brown flowers in number no less than 355; and another object of much interest to cultivators was a handsome pan of *Pleione humilis* exhibited by Sir Trevor Lawrence (Mr. Spyer, gr.). Many other plants of interest were shown, of which detailed notice is given further on.

The proceedings of the Fruit Committee call for no special remark. At the Scientific Committee the special feature of interest was Mr. Smith's interesting and suggestive paper on a fungus disease affecting grass, and possibly injurious to animals also. The cut blooms of *Sikkim Rhododendrons*, together with the remarks thereon by Mr. Mangles, were highly appreciated by the members.

SCIENTIFIC COMMITTEE.—Dr. Maxwell T. Masters, F.R.S., in the chair.

Malformed Oaks.—Dr. Masters reported that the specimens sent to the last meeting by Mr. F. Moore from the Isle of Wight probably owed their peculiar appearance to some agency (insects?), which had injured the tip of the fruit-spike and arrested growth, so that the acorns, instead of being separated one from another by marked intervals, were crowded together into one mass, giving the appearance of proliferation.

Disease of Thuysa.—Mr. W. G. Smith exhibited specimens of *T. compacta* attacked by the Australian fungus named *Capnodium australe* by Dr. Montague. *Thuja compacta*, aurea, and elegantissima are sometimes covered by this *Capnodium* in autumn and in the following early spring are found to be quite dead, the roots as well as the tops. The fungus was described by Mr. Berkeley in the *Journal of the Royal Horticultural Society*, vol. iv., p. 253, as surrounding the branches of conifers from the Swan River. An illustration of this fungus is given by Mr. Berkeley at p. 259 of the volume referred to.

Disease of Grass.—During the last two years (said Mr. Smith) the grass of Sussex, and especially that of Kent, has been attacked by a curious and, as regards this country, probably new fungoid disease. The grass attacked by the fungus (*Isaria fulfiformis*, B.) is popularly believed to be capable of causing the death of such animals as feed upon it. As far as is known, the disease has only been known for certain as British for little more than two years; it came into prominent notice in Kent in September, 1880. One person, however, a Kentish gardener, states that he has known the disease for twenty years.

The grasses it chiefly attacks are the *Festucas*, and chiefly perhaps *F. ovina*. The fungus grows most plentifully on sandy soils, it is not uncommon in chalky positions, but it is apparently absent from clay soils. It does not appear on young grass, but on the old. It is first seen about September, and fades away about the following January. In a damp, warm winter like the present, the fungus remains much longer in the fields, so that even now, in the month of March, the fungus can still be found.

The general appearance of the fungus (fig. 56) may be aptly compared with fine short tufts of minute scarlet or crimson seaweed. The tufts spring from an effused, mucous, pinkish mycelium, which has a tendency to glue different parts of the attacked grass together. These fine threads or tufts grow on the leaves and stem, from which they break away and then fall to the ground. The fungus might from the notice have been overlooked had it not been for the brilliant red coloration—in this it resembles pink coral. As with the fungus of the Hollyhock disease and the disease of *Thuysa*, this new pest of grasses appears to be of Australian origin; it is described by the Rev. M. J. Berkeley amongst Australian fungi in the *Journal of the Linnean Society* for 1873, vol. xiii., p. 175, under the appropriate name of *Isaria fulfiformis*. Mr. Berkeley describes it as growing "on some germinating cereal" from Mount Gambier, and states the colour to be pallid. Mr. Berkeley himself, however, identifies the English plant as the same with the Australian one, the only difference apparently being that of the colour. Dr. Cooke in March of last year announced the fungus as British in *Grevillea*, vol. ix., p. 94. Mr. Berkeley's description is "pallid, slender, filiform, sparingly branched, branches acute, spores very minute, globose."

This description, with the exception of the colour, is very precise, and exactly agrees with the *Isaria* plants of our illustration, made from nature (fig. 58), and enlarged five diameters. The solid black parts of the drawing are in Nature crimson: this tint seems to be permanent, at any rate the colour remains perfectly unchanged in dried specimens for several months.

The microscopic structure of the fungus is very simple, it is one compacted mass of cells, the larger

Reports of Societies.

Royal Horticultural. Col. Trevor Clarke in the chair. The Rev. G. Henslow first directed attention to a beautiful series of cut blooms of true Himalayan species of *Rhododendron*, cultivated by Mr. Mangles, and which were exhibited at the meeting of the Scientific Committee. He next called attention to the collections of *Cyclamens* exhibited, and specially to two fine plants, a pure white and a pure crimson, both obtained from "The Gem," which received a Floral Certificate from the Royal Botanic Society in March, 1879, and grown by Mr. Little. The lecturer remarked on the effects of crossing, and alluded to the curious habit of *Cyclamens* in burying their pods to acquire additional nourishment. He then called attention to some remarkable malformations—a *Primrose* with a green corolla, shown by Mr. Draper, of Seaham Hall, and a Chinese *Primrose* with a foliaceous calyx, and he pointed out that a flower is only a metamorphosed group of leaves which in these cases were, so to say, asserting themselves. A curious profliferous form of *Anthurium Scherzerianum album*, with every flower at the base of the spadix replaced by a miniature spadix in a small white spathe of bloom, exhibited by Mr. Child, was next commented on, and its resemblance to a similar process in Egyptian Wheat, which bears several ears on one stalk, was pointed out. Mr. Henslow took the opportunity to correct the popular error that Wheat found in the catcombs of Egypt and called "Mummy Wheat," and probably 3000 to 4000 years old, ever germinated; this being confounded with the former, which is occasionally grown in this country, has led to the mistake. He stated that he had sown Wheat apparently quite sound, but seventeen years old, and not a grain germinated.

At the conclusion of the lecture it was proposed and seconded, and carried unanimously (with three cheers, led off by the Chairman), that an address be sent to the Queen, the Patron of the Society, heartily congratulating Her Majesty on her recent peaceful escape from assassination.

The Council-room well filled with gay and interesting plants, a strong muster of the several committees, and a fair attendance of visitors, augur well for the coming season. The main features which struck the eye on entering were fine collections of

but so much to the general effect, are alluded to elsewhere, as also the collection of pedigree Roses sent by Mr. Bennett. The Tea characteristic was strikingly manifest in the perfume of these Roses. Whatever may be the ultimate verdict of specialists on these plants Mr. Bennett's procedures are methodical and worthy of commendation as an attempt to

cells occupying the centre of the branches, and the smaller ones the outside; as the smaller outside cells gradually reach the tips of the branches they break up into innumerable extremely small globose spores, conidia, or seeds, as shown at the upper part of fig. 58, enlarged 320 diameters.

This *Isaria* disease on grass is supposed by many persons in Kent to be capable of killing cattle. In September, 1880, an instance occurred where two cows died from an affection of the lungs, and when a *post-mortem* examination was made it was found that the lungs were covered with a fungus-like material, not unlike, it is said, the fungus which attacks the throat in diphtheria. The veterinary surgeon who conducted the examination declared his opinion that this fatal ailment had been contracted from the *Isaria*-infected grass. The same doctor is said to have led two rabbits on infected grass only, and that they both died therefrom. It is necessary to say that these two cases are far from proved; at the same time it would not be wise to immediately say that cases of this nature are impossible. In favour of the doctor's view it may be said that some members of the order *Isariaceae* grow upon decaying animal substances, chiefly hymenopterous insects; sometimes these insects are, however, in a living state. *Isaria farinosa* grows on dead pupae, *I. arachnophila* on dead spiders, and *I. sphingum* on dead moths. These creatures are, however, attacked while in a living state. The genus *Isaria* is supposed to be a sort of conidiophorous or larval condition of the genus *Torula* (or *Cordicipes*) amongst fungi; several British species of this genus grow on the pupae and larvae of moths, one grows on an ichneumon, and another (*Cordicipes sphaeroccephala*) upon living wasps (*Glyptus vegetans*) in the West Indies. This fungus seems to have no place at present in lists of British fungi, yet it seems probable that the fungus now exhibited and growing from the body of a bee is no other than that species (fig. 57). The bee was caught in this country as it was inconveniently lying with its fungus burden. An allied fungus, named *Microcera coccophila*, is parasitic on coccæ. These instances were mentioned by Mr. Smith, not with the idea of showing that *Isaria faciciformis* is capable of killing cattle, but to indicate that members of the order really can and do grow upon living animal substances; added to this, it may be stated that *Torula*, which is the same as *Isaria*, is the next genus to *Claviceps* or *Ergot*, and that the genus *Isaria* is at present imperfectly known and understood, so that there is a good opportunity in this case for original observations.

For the specimens of infected grass exhibited and for a considerable part of the information contained in these notes, Mr. Smith acknowledges his indebtedness to the Rev. Chas. W. Shepherd, of Trottscliffe Rectory, Maidstone.

PLANTS EXHIBITED.

Mr. Elwes showed flowers of *Azollaolina Severacovi*, which, in place of the ordinary dark purple colour of the normal flower, were seen to be green with a dark centre only.

Frillillaria obliqua?—A species supposed to be of Russian origin, but concerning which nothing definite is known; it has very dark purple flowers and twisted leaves.

Mucori Elwesii, a species also of uncertain origin, with small compact spikes of deep blue, bell-shaped flowers edged with white.

Leucium strivum var. *pubellum*.—A variety which Mr. Elwes has cultivated for some years, and which constantly blooms much earlier than the type. Mr. Mangles recognised it as having seen it in the South of France.

Chimaphila pallida.—Mr. Elwes showed specimens of this from self-sown seeds, the seedlings having flowered in the second year. "In Asia Minor, the plant," says Mr. Elwes, "comes up with a rush" immediately after the melting of the snow, and is of compact habit, with short pedicels, while in this country, owing to the slower growth, from our variable climatal conditions, the habit is laxer and the pedicels much shorter.

Sativium indicum, from Nepal, is a terrestrial Orchid, with a close spike of pinkish flowers, of which an illustration will shortly be given in the *Botanical Magazine*.

Rhododendron.—Mr. Mangles showed cut flowers of *R. argenteum* (syn. *R. grande*) with noble foliage, the leaves lanceolate, silvery beneath, the flowers white, in fine terminal trusses, each individual flower having the appearance of a *Frostlingian* Lily of the Valley. The species is very variable, and the specimens shown were much superior to those figured in Sir Joseph Hooker's *Rhododendrons of Sikkim Himalaya*. *R. Hookeri* is a species discovered by Doth in Bootan, allied to *R. Thomsoni* in the colour and form of the flowers, but with rows of scales along the nerves on the underside of the leaves. Mr. Mangles obtained his plant from Mr. Anderson-Henry. *R. ciliatum*, showing something of the lilac tint of the one figured in the *Rhododendrons of Sikkim*, but the

uniform lilac coloration of which is now believed to have been a mistake. *R. pendulum*, a dwarf trailing epiphyte with the habit and appearance of *Edgeworthia* on a smaller scale. *R. fulgens*, a species found at great elevations, and hence comparatively hardy; *R. arboreum*, a very variable species; *R. Falconeri*, a species nearly allied to *R. grande* (*argenteum*); and *R. daburicum*, the species figured by us last week. A vote of thanks was unanimously accorded for the splendid exhibit and the interesting account which accompanied them.

Oreocnifera.—Dr. Masters showed specimens of the cones and foliage of several species collected for Messrs. Veitch, and which will be further alluded to in our next issue. The *Fascia* noted on a smaller scale. *R. fulgens*, a species found at great elevations, and hence comparatively hardy; *R. arboreum*, a very variable species; *R. Falconeri*, a species nearly allied to *R. grande* (*argenteum*); and *R. daburicum*, the species figured by us last week. A vote of thanks was unanimously accorded for the splendid exhibit and the interesting account which accompanied them.

Botanical Certificates were awarded to the *Neurothallis glossopogon*, remarkable among its genus for its large flowers, the segments of which are 3 inches in length, the leaves, at first prolonged into a narrow, then slender tail, as in some of the *Masdevallias*. The lip is small, oblong, chocolate-coloured, with a fringe of hairs at the tip. A similar award was made to the beautiful *Spathoglottis Lobbi*, a plant with a very slender, wiry flower-stalk, with a single flower 1½ inch in diameter, clear canary-yellow, with broad ovate segments, and a lip with a narrow stalk and a spoon-shaped blade.

FLORAL COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. The subjects of greatest interest introduced to public notice on this occasion, and which received awards from the committee, were *Amaryllis Duchess of Connaught*, a medium-sized white of beautiful form; *Amaryllis Charles Dickens*, a fine bold flower, with broad smooth overlapping segments, scarlet in colour with a white longitudinal band in the centre of each; *Amaryllis Baron Schroeder*, a flower of excellent shape, and remarkable also for its intense crimson-red colour; *Rhododendron Charles Dickens*, a Princess Alexandra × *Duchess of Edinburgh*, a most pleasing novelty with a large truss of orange-salmon coloured blossoms; *Rhododendron Escobier*, a Princess Royal × *javanicum*, a very fine hybrid, with large flowers of a salmon shaded buff colour with reflexed lobes; and *Oncidium fuscatum album*, a variety with a broad white lip, having a large lilac blotch in the centre, all from the nurseries of Messrs. James Veitch & Sons; *Galeandra nivalis*, a remarkable and rarely seen Orchid, from Sir Trevor Lawrence, with erect slender, spike-shaped, glaucous pseudobulbs and grassy foliage, and flowers in racemes, each flower having narrow, reflexed, rich olive segments and a funnel-shaped lip, the fore part expanded into a broad, flat white lobe, with a large central violet blotch. *Odontoglossum crispum* var. *Stevensi*, from Mr. Stevens, Tientham, a form with flowers measuring 3 inches across; sepals oblong-lanceolate, petals of the same form but waved at the edges, heavily bearded, and spotted with brown; lip oblong-ovate with a clear yellow disc. *Cyclopogon glandulosus* with flowers 1½ inch in diameter, starry in outline, clear white, with the front lobe of the lip ovate acute, and white with yellow lines, from Mr. Parr, gr. to Mrs. Russell Sturgis, Givon's Grove, Leatherhead. *Cyclamen*, *White Gem*, *Crimson Gem*, and *Rosy Morn*, from H. Little, Esq. (see p. 370); *Abutilons* *La Grande* and *Cloth of Gold* from Mr. George (see p. 370); and *Cineraria* Mr. Collingford, a large, handsome, reflexed, and of a rich crimson colour, with a shade of lake round the disc—from Messrs. H. Cannell & Son, Swanley. The Messrs. Veitch also had a flowering plant of the ivory-white *Phalenopsis tetraspis*, mentioned last week; *Dendrobium micans*, said to be a hybrid between *D. lituidorum* and *D. Wardianum*, but presenting only the appearance of a poor *D. Itinulium*; *Loropetalum chinense*, an old but valuable hardy Chinese shrub, allied to *Hamamelis*, but with linear white petals, and leaves like those of *Ficus repens*; *Abelia serrata*, a pretty half-hardy shrub, with slender branches, small ovate leaves, and pale flesh-coloured, funnel-shaped flowers; *Rhododendron Early Gem*, an admirable variety for early forcing; and *Cydonia japonica alba*, a pure white-flowered variety of great beauty and usefulness. Messrs. Paul & Son, Chessington, showed some well-flowered half specimen Roses, nice examples of such well-known sorts as *Anna Alexieff*, from France, *Madame Victor Verrier*, *Madame Lacharme*, *Princess Mary of Cambridge*, *Madame de St. Joseph*; and with these were also some well-flowered small *Giant Azaleas* and a new perpetual *Polyantha* Rose named *Mignonette*, dwarf and neat in habit as a Fairy Rose, with double peach-coloured blossoms. Mr. John Odell, Horist, Gould's Green, Hillingdon, had Mr. Williams' *Primula alba* magni-

fic, and another good white named *Purity*; and Mr. P. S. Williams had a choice group of his fine strain of gigantic *Cyclamens*. The superb *Cineraria* *March Past* and other fine varieties, together with purple and white *Violets*, the latter *Swanley White*, and the finest double white yet introduced; and *Polyanthas* James Douglas, a dark ground, gold-laced flower, with very bright and clearly defined lacing, came from Messrs. Cannell & Son. Mr. Salter, gr. to J. Southgate, Esq., Streatham, had a small flowering plant of *Dendrobium Brymerianum*, the species so remarkable for its clear yellow flowers with deeply ringed and bearded lip. Mr. Bennett, of Shepperton, had a nice lot of cut blooms of some of his pedigree Roses, and flowering plants from the graft of Lady Fitzwilliam and Earl of Embroke, both unmistakably showing the Tea cross, the latter especially both in foliage and scent, and which should, moreover, be welcomed for its fine dark colour. *Narcissus bulbocodium*, a form with paler sulphur-yellow coloured flowers than the ordinary Hoop-pettucoot *Narciss*, came from Mr. Nares, gr. to L. D. Llewellyn, Esq., Atherton Grange, Wembleton. Amongst interesting plants shown in a cut state must be included *Cineraria* *Welbiana*, with narrow violet-pink ray florets, and curious as being found wild in the Canary Islands only; *Anemone capensis* with very deeply cut rigid dark green evergreen Parsley-like foliage, and large lilac flowers; and *Ariscama Sieboldii*, with bold 3-lobed leaves and purple spathes incurved at the tip, all grown and exhibited by Mr. Green, gr. to Sir G. Mackley. Very fine blooms of double-flowered *Cinerarias* of various colours, from Mr. Vertegans, of the Chad Valley Nurseries, Birmingham; those of *Vorigen*, bright rose-purple; *Edgastonia*, dark rose-purple; and *Purple Perfection*, a bunch of *Violets* in miniature, being especially commendable. A pretty rose-coloured variety of *Rhododendron* in the way of *R. Nobleanum*, grown in the open air, from J. J. Whible, Esq., Bulmershe Court, Reading; very beautiful blooms of various varieties of *Rhododendrons*, all from the open air, and sent by Mr. Martin, The Drake, St. Austell, Cornwall; delicately scented blooms of the fine white *Hymenocallis macrostaphana*, from Mr. Woodbridge, Syon House; seedling Tree *Carnations*, of bright colour, good form, and grateful odour, from Mr. Turner, of Slough; and *Violets*, blue and white, the latter *Swanley White*, the finest double white variety yet introduced, from Messrs. Cannell & Son.

First-class Certificates.

To Messrs. Veitch & Sons, for *Amaryllis Duchess of Connaught*.

To Messrs. Veitch & Sons, for *Amaryllis Baron Schroeder*.

To Messrs. Veitch & Sons, for *Amaryllis Charles Dickens*.

To Messrs. Veitch & Sons, for *Rhododendron Escobier*.

To Messrs. Veitch & Sons, for *Rhododendron Monarch*.

To Messrs. Veitch & Sons, for *Oncidium fuscatum album*.

To Mr. Stevens, for *Odontoglossum crispum Stevensi*.

To Sir Trevor Lawrence, Bart., M.P. (Mr. Sperry, gr.), for *Galeandra nivalis*.

To Messrs. Cannell & Son, for *Cineraria* Mr. Collingford.

To Mr. George, for *Abutilon* *La Grande*.

To Mr. George, for *Abutilon* *Cloth of Gold*.

To H. Little, Esq. (Mr. Wiggins, gr.), for *Cyclamen persicum* *Crimson Gem*.

To H. Little, Esq., for *Cyclamen persicum* *White Gem*.

To Mr. Parr, for *Cyclopogon glandulosus*.

Second-class Certificate.

To H. Little, Esq., for *Cyclamen persicum* *Rose Queen*.

Cultural Commendation.

To J. C. Baines, Esq. (Sperry, Cinkabury), for a specimen of *Lycastris tuberosus*, with 225 blooms.

To Sir T. Lawrence (Mr. Gyles, gr.), for handsome pan of *Bleone bunulis*.

Medals.

Silver-gilt Flora to H. Little, Esq., for group of *Cyclamens* and *Cinerarias*.

Silver Flora to Mr. H. B. Smith, Ealing Dean, for group of *Cyclamens*.

Silver Flora to Messrs. Paul & Son, Chessington, for a group of pot Roses.

Bronze Banksian to Mr. B. S. Williams, for a group of *Cyclamens*.

FRUIT COMMITTEE.—H. J. Veitch, Esq., in the chair. At this meeting seedling Apples, the *March Queen* and *Barnack Beauty*, from Mr. Gilbert, of Buryleigh, and *Henry Webb*, from Mr. Laxton, of Bedford, were submitted for judgment, but were not considered improvements on existing sorts. Mr. Tatham, Bushy Down, Tooting Common, sent some French Bees named *Australian Prolific*, which were stated to be four days earlier, under the same treatment, than *Osborn's Early Forcing*, the results perhaps of the seeds having been ripened in an earlier climate. Mr. Barter, of the Ilfracrow Road, again brought some good *Mushrooms*, grown in the open-air beds.

Notices of Books.

On and Off Duty; being Leaves from an Officer's Note-book. By S. P. Oliver, late Captain R.A., &c. With Illustrations by the Author. London: W. H. Allen & Co.

Too often we lay down books of travel with a feeling of sorrow, if not of downright vexation, that it should have fallen to the lot of the author to have had opportunities of travel and observation which he could not, or did not, turn to any good account. It is not indeed to be expected that every traveller can be a trained observer capable of recording faithfully all he sees, of whatever nature, or a writer skilled in the art of laying before his readers clear and vivid accounts of what is most noteworthy. Nevertheless, the reader has a right to expect in all and every case an intelligent and faithful narration, while absence of detail relating to particular subjects is readily overlooked if the writer is careful to avoid writing about what he has no knowledge of. Anything more aggravating, for instance, to the reader desirous of obtaining some information as to plants and the particular conditions under which they grow than the way in which some writers allude to the subject can hardly be conceived. Only the other day we had occasion to comment on the raptures of one traveller over the Bougainvillea in Madeira—raptures justifiable enough in themselves, but which rendered the writer ridiculous when he went on to assert that the plant could not be grown in England, all oblivious of the fact that there are few conservatories in the kingdom of which the plant does not form a chief ornament.

Captain Oliver is no such traveller. Although he modestly disclaims any reputation as a man of science it is abundantly clear that his natural faculties and tastes, aided, no doubt, by his military education, have made him an excellent observer. His information is so extensive, his appreciation so catholic that every page betokens a well-read and keenly observant man, with sympathetic appreciation of the questions which are uppermost in scientific circles. With some exceptions the places visited by Captain Oliver are now so well known that a passing visitor has little chance of hitting upon anything not already thrice chronicled. Over the most well-trodden ground, however, Captain Oliver proves himself a delightful and cheerful companion, even on the look-out for what is noteworthy, and always keenly appreciative of the humor of the situation. But Captain Oliver has to tell, not only of Malaya, Ceylon, and of Chinese and Japanese seaports, but of the much less generally known districts, such as Madagascar, Réunion, St. Helena, and Central America. Captain Oliver's travels extended over many years, so that his narrative suffers in some cases from the delay that has taken place in its publication. This is notably the case in reference to Japan, the author's account of which seems meagre by the side of the more recent and complete narrative of the opening up of the country has rendered possible. On the other hand, for the very reasons we have mentioned, Captain Oliver's book will have a distinct historical value; and as the old order is rapidly changing, his faithful account of things as they were will be so much the more valuable. The visit to Tsing Yuen and Peking soon after the Treaty of Tientsin, and to Yeddo, soon after the attack on the Legation, are instances in point; at that time there was much truth in the saying that "a night at the Legation at Yeddo was not unlike a day's duty in the trenches before Sebastopol."

Perhaps the most novel part of Captain Oliver's book is the chapter relating to Réunion. In that island the author partook of the "Palmette" or Cabbage Palm—a circumstance we allude to here because one of our correspondents, a traveller also, lately threw doubts upon the frequency of the use of the "Cabbage," upon which account we quote from the volume before us— "There were several kinds of vegetable, but Palmette predominated, and both as a salad and au gratin it was excessively good. These Palmettes or Cabbage Palms are cultivated extensively in Bourbon for the sake of their *chou* [chou] or Cabbage. . . There are three descriptions of the Chou Palmette, viz., *Arecia alba*, *A. crinita*, and *A. rubra*. The tree is cut down to obtain the soft tender shoot in its spathe which forms the Cabbage. But the thrifty horticulturists never cut down one tree without planting another, and they have them planted in rows in succession, in order that as the tree arrives at its early maturity for the table, there are others ready to take its place." On the other hand one *Arecia*, *A. lutescens*, is reputed poisonous; its glaucous colour of its foliage, and the bitter taste of its Cabbage render it readily recognisable. The occurrence of a poisonous species is noteworthy among Palms.

Captain Oliver has taken pains to insert from the narrative of more recent travellers fuller details where thereat of the subject demands it, while by his copious and well selected references to writers on the geology, natural history, and ethnology of the countries visited, he has rendered his work a veritable book of reference, of the more usefulness as it is provided with an index. But we are trespassing on the patience of our readers, for it is not Captain Oliver known to them as the author of many notes in these pages, and have they not been enriched by numerous singularly effective representations of tropical scenery and vegetation from his skilful pencil, many of which are reproduced in the present volume? To such a friend no introduction is needed; many, however, will be glad to learn that the versatile and accomplished author's narrative is now published in a separate and much extended form of the only defect in which, so far as we see, is a lack of condensing power, several statements of interest only to the author or his immediate friends being allowed to be made public.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, MARCH 15, 1882.

Table with columns: MONTH AND DAY, BAROMETER (Mean Reading, 30° Fahr., 18° Réaumur), TEMPERATURE OF THE AIR (Range, Highest, Lowest, Mean for Day, Mean for Month from average of 30 years), Hygrometric (Degree of Sat. in 100), WIND (New Point, Direction, Force), and RAINFALL (Average, in 24 hours). Rows for Mar 10-14 and a weekly mean.

- Mar. 10.—A fine warm day. Overcast. Mild night.
11.—A fine warm day. Overcast. Fine warm night.
12.—A fine morning, fog and darkness in the morning, rain all the evening.
13.—A fine morning, fog and darkness prevailed for a time. Fine night.
14.—A very fine bright day; sun shining brightly. Fine night.
15.—A very fine bright day; sun shining brightly. Fine night.

LONDON: Atmospheric Pressure.—During the week ending March 11, the reading of the barometer increased from 29.77 inches at the beginning of the week to 29.80 inches by 9 A.M. on the 5th, decreased to 29.58 inches by midnight of the same day, increased to 29.28 inches by midnight of the 6th, decreased to 30.23 inches by 3 P.M. on the 7th, increased to 30.27 inches by 9 A.M. on the 8th, decreased to 30.24 inches by 3 P.M. of the same day, increased to 30.37 inches by 9 A.M. on the 9th, decreased to 30.29 inches by midnight of the same day, and was 30.46 inches at the end of the week.

The mean reading for the week at the level of the sea was 30.19 inches, being 0.85 inch higher than last week, and 0.05 inch above the average of the week.

Temperature.—The highest temperature in the shade in the week was 55° on the 8th and 10th. On the 6th the highest temperature reached was 49°.5. The mean of the seven high day temperatures was 53°.

The lowest temperature in the shade in the week was 36° on the 7th; on the 10th the lowest temperature was 48°.5. The mean of the seven lowest temperatures was 43°.2.

The greatest range of temperature in one day was 16°.5 on the 7th; the smallest was 5°.8, on the 9th. The mean of the seven daily ranges was 9°.8.

The mean temperatures were, on the 5th, 46°.5; on the 6th, 43°.8; on the 7th, 45°.8; on the 8th, 50°.8; on the 9th, 50°.7; on the 10th, 51°.4; and on the 11th, 48°.8. And these were all above their averages by 6°, 3°.3, 5°.3, 10°.3, 10°.2, 10°.8, and 8°.1, respectively.

The mean temperature of the air for the week was 48°.3, being 3°.6 higher than last week, and 7°.7 above the average of the week.

The highest reading of a thermometer with black-

ened bulb in vacuo, placed in the full rays of the sun, was 82°.5 on the 9th; the highest on the 7th was 54°. The mean of the seven readings was 67°.

The lowest reading of a minimum thermometer with its bulb placed on grass and fully exposed to the sky was 38°.0, on the 7th. The mean of the seven readings was 38°.0.

Rain.—Rain fell on two days to the amount of 0.19 inch.

ENGLAND: Temperature.—During the week ending March 11 the highest temperatures were 67° at Sunderland, 65° at Sheffield, and 62°.4 at Nottingham. The highest temperature at Blackheath was 55°, at Plymouth 55°.3, and at Bristol and Bolton 50°.5. The general mean was 50°.1.

The lowest temperatures in the week were 29° at Hull, 29°.5 at Wolverhampton, and 30°.7 at Bolton. The lowest temperature at Truro was 43°, at Bristol 38°.5, and at Liverpool 38°.4. The general mean was 34°.7.

The greatest ranges of temperature in the week were 35° at Sunderland, 31° at Hull, and 30°.8 at Nottingham. The least ranges were 17° at Truro, 18° at Bristol, and 18°.4 at Liverpool. The general mean was 24°.4.

The mean of the seven high day temperatures was highest at Sunderland, 62°.5, at Cambridge 57°, and at Truro, 56°.3; and was lowest at Bolton, 52°.8, at Bradford 52°.5, and at Brighton, Blackheath, and Wolverhampton, 53°. The general mean was 54°.6.

The mean of the seven low night temperatures was highest at Truro, 47°, at Plymouth 45°.5, and at Bristol 45°.4; and lowest at Hull, 37°.6, at Wolverhampton 39°.5, and at Sunderland 39°.8. The general mean was 42°.3.

The mean daily range was greatest at Sunderland, 20°.7; at Hull 17°.7, and at Nottingham 15°.5; and was least at Bristol and Plymouth, 8°.2, and at Truro, 9°.3. The general mean was 12°.3.

The mean temperature for the week was highest at Truro, 50°.9, at Cambridge 49°.7, and at Sunderland 49°.4; and was lowest at Bolton, 44°.8, at Wolverhampton 45°.4, and at Hull 45°.8. The general mean was 47°.7.

Rain.—The largest falls were 0.46 inch at Liverpool, 0.45 inch at Bolton, and 0.43 inch at Plymouth and Bristol. The smallest falls were 0.03 inch at Leicester, 0.05 inch at Sunderland, and 0.07 inch at Nottingham. The general mean was 0.23 inch; it fell on an average of from three to four days.

SCOTLAND: Temperature.—During the week ending March 11 the highest temperature was 57°.6, at Aberdeen; at Greenock the highest temperature was 53°. The general mean was 55°.4.

The lowest temperature in the week was 29°.2, at Aberdeen; at Paisley the lowest temperature was 33°.5. The general mean was 30°.0.

The mean temperature for the week was highest at Paisley, 46°.2; and lowest at Greenock, 42°.5. The general mean was 44°.5.

Rain.—The largest falls were 2.74 inches, at Greenock, and 1.81 inch at Paisley; the smallest was 0.35 inch at Aberdeen. The general average fall was 1.35 inch.

JAMES GLAISHER, F.R.S.

Enquiries.

He that questioneth much shall learn much.—Bacon. I.E. STORING IN SAWDUST.—Has any antiquary among your correspondents traced this practice to an earlier date than the casual experiment recorded in your journal for January 10, 1881, pp. 20 and 38? A. M. A.

POMEWATER.—I am anxious to ascertain about the word "Pomewater." It is the name of a kind of Apple made use of some two hundred years ago medicinally. Will you tell me what it means? Can you refer me to any book which will tell me about this variety of fruit? Webster states it—"Pomewater, a sweet juicy Apple." Hope as a Pomewater? Shakespeare: Love's Labour Lost. See also a Pomewater? Where the medicinal virtues are enlarged upon. This Apple, which is now not known, is also the subject of comment in Mr. Elliscomb's Plant Lore of Shakespeare. Also, what is meant by "Pomum Canisum"? What does the adjective "canisurium" as used of Apples, thus,—"Take of 'Pomum canisurium' 2. J. W. G.

Answers to Correspondents.

- ANEMONES: H. Loth. Fine varieties of Anemone hortensis and A. coronaria.
AZALEA APOLLIS: J. Hoskin, Toronto. It is quoted in the Catalogues of the Nurserymen who grow greenhouse plants for sale, and we should think would be no difficulty in getting it from any leading nurseryman in the States.
"CHARITY": E. W. Pamplin. The plant popularly called Charity is Polemonium ceruleum.
ERRATUM.—At p. 258, in the paragraph on Plant Labels, for "painted" labels, read "pointed" labels.
GOOSEBERRY CULTURE IN LUZERN: J. W. For

anything we know the Gooseberry ought to grow quite well in the canton of Lucerne.

HYACINTH MALFORMED: C. L. S. A very common occurrence.

NAME OF APPLE: H. H. Emperor Alexander.

NAMES OF PLANTS: A. M. We cannot name florists flowers. You should take them to some nursery where Camellias and Azaleas are made a specialty. — Z. M. Hellobonus viridis. — H. G. H. We are glad to assist so far as we can consistently with our more paramount engagements, but we cannot undertake to name sixteen wretched specimens, even though they be common Grasses. No. 3 seems to be Agrostis vulgaris; 4, Bromus mollis; 5, Dactylis glomerata; 6, Avena sativa; var. bulbosa; 8, Glycyrrha fluitans; 16, Aira caespitosa. — C. M. Your plant is the Snail-podded Medick (Medicago scutellata), not the Oyster-plant, so called, which is Salsify (Trigonotis pedunculata). — F. H. 1799. One of the more finely cut forms of Asplenium Adiantum-nigrum (the Black Maidenhair Splenwort).

ORCHIDS AU NATUREL: Orchid Grower. What was intended was simply that the plant spoken of is grown in such a way as closely to imitate natural conditions, being pendulous from a slab of wood or bark, as if growing upon a tree.

PEACH BLOOMS NOT SETTING: Gardener. We cannot tell you, in the absence of any details as to the manner in which you have been treating the trees. If they are in a proper state as regards moisture at the roots, and the atmosphere has been kept warm and bracing, there should be no difficulty; though of course you cannot expect them to do so well as those more favourably situated.

PRIMULA: S. K. A poor form of Chiswick Red.

SENECIO SPATHULIFOLIUS: C. H. D. According to Prof. Babington (Journal of Botany, February, 1882) this is distinct from S. compositus. You can refer to the catalogue in question, the compiler being an authority on such questions.

COMMUNICATIONS RECEIVED.—J. H. B., Mentone.—C. G., Pendell Court, not uncommon.—M. Lafosse, who are greatly obliged for your interest in the subject. You can refer to the reproduction used to great (—) J. W.—Stiffard.—W. D.—G. F. W.—E. H.—E. M.—W. G. M.—N. S.—H. M. E.—H. F. W.—I. W.—J. S.

DIED, at Mid-Yell, Shetland, on the 7th inst., WILLIAM DALRYMPLE PATERSON, L.R.C.S., and L.R.C.P. Edinburgh, eldest son of Dr. Paterson, Bridge of Allan. All friends will kindly accept of this the only intimation.

Markets.

COVENT GARDEN, March 16.

The fine weather is bringing early forced fruits and vegetables in large quantities to our market, and prices have considerably fallen all round, Grapes alone making their full value. James Webber, Wholesale Apple Market.

CONTINENTAL COMPANY OF HORTICULTURE

(Formerly J. LINDEN),
52, RUE DU CHAUME, GAND. 5, RUE DE LA PAIX, PARIS.

NEW "BEDDING-OUT" PLANT,

ANNOUNCED FOR THE FIRST TIME, AND WHICH WILL BE SENT OUT ON APRIL 1, 1882. ORDERS WILL BE ATTENDED TO CONSECUTIVELY.
GYNURA AURANTIACA.

The eminent botanist of the Royal Kew Herbarium, Mr. N. E. Brown, speaks thus of this beautiful plant in the ILLUSTRATION HORTICOLE for 1881, the last part:—
"The Gynura aurantiaca is a hardy plant belonging to the Compositae, and is of such an ornamental character as to allow of one's saying that it is not surpassed by any other plant of the same class. The stem and leaves are clothed throughout their entire length with a thick covering of hairs, soft to the touch, and of a beautiful deep violet colour, which gives an appearance of richest velvet to the plant. This is more especially the case with the young leaves, and, when combined with the brilliant orange of the flowers, the aspect of the plant is truly superb."
Without doubt it will gain great favour as an ornamental plant for the open borders."
As this plant in all probability will become as popular as Iresine Lindeni and Coleus Verschaffeltii, both sent out by this establishment, it will be sent out at a very low price in order that it may spread as rapidly as possible.

Two plants 10s., 50s. per dozen.
Orders will be booked from to-day, and all communications must be addressed to

THE COMPAGNIE CONTINENTALE D'HORTICULTURE, 52, RUE DU CHAUME, GAND.
The Illustrated CATALOGUE (English Edition) of NEW PLANTS will appear on April 1 next.

NATIVE GUANO,
 SUITABLE FOR ALL CROPS.

Price, £3 10s. per Ton, in Bags, at Aylesbury.

A single x cut, Sample Bag sent, Carriage Paid, to any Railway Station upon receipt of Post-office Order for 5s.

This valuable Manure, prepared from Sewage by the "A. B. C." process, has been extensively used for several years, by Farmers, Gardeners, and others, whose reports testify to its fertilising properties.

EXTRACTS FROM LAST SEASON'S REPORTS:—

WILLIAM CRUMP, Gr. to Duke of Marlborough, Blenheim Palace Gardens, December 12, 1881.

"Used for Vines, Peach trees, and other fruit trees, also Potatoes, Carrots, Parsnips, Onions, &c. Results: satisfactory. Fruit trees assumed rich dark green foliage, increased vigour, whilst the fruit swelled up to a very fine size. Potatoes came out in splendid condition; other roots were benefited by its application. No other manure used. Native Guano. Undoubtedly a valuable fertilising agent, and I shall lose no opportunity of recommending it to gardeners and others."

A. BLAIR, Head Gr. to H. Cameron, Esq., The Lilies, Woodon, January 3, 1882.

"Used for Peas, Potatoes, Onions, Cabbage, Cauliflowers, Celery, Vines, Cucumbers, &c.; Chrysanthemums, Primulas, Geraniums, Fuchsias, &c. Results: Onions, Cabbage, Cauliflowers, and Peas good; Cucumbers, first-rate; Potatoes, a good crop, and I consider it a good manure for pot plants. I think the Native Guano only requires to be more known to the public to be largely used."

Sixteen Prizes awarded at Birmingham Show, 1881.

The Annual Show of Farm and Garden Produce, grown with Native Guano, will be held at Aylesbury in October next. Schedules and Prizes and all particulars, together with testimonials, &c., may be obtained upon application to

The Native Guano Company (Limited), Aylesbury, Bucks.

WILLIAMS' NEW HOTHOUSE SHADING.

The most suitable for Shading Orchids, Ferns, Palms, Stove and Greenhouse Plants.

After several years' successful trials at home, I have much pleasure in bringing this article before the notice of Orchard Growers, as being better adapted to the culture of Orchids and other plants than any other Shading. It is largely used by R. Warner, Esq., of Chelmsford, and many other successful cultivators of Orchideaceous Plants.

It is a strong durable Cotton Netting, woven in squares, so close as to exclude the direct rays of the sun, but at the same time admitting the greatest amount of light attainable through Shading. It withstands the weather better than any other class of Shading, and may be used beneficially during cold weather to keep the frost out, on account of the thickness of its texture. It stands exposure much longer than canvas, and is altogether a better article. It is astonishing to see the difference in the growth of Orchids shaded with this material, and those shaded with canvas; in the one case the plants receive the greatest amount of light attainable through Shading, and consequently grow more robust, and produce stronger spikes and better coloured flowers—in the other the plants are drawn up, the houses appear quite dark, the spikes become slender and weak, and the plants in many cases do not flower at all.

Blinds made up to any size and fixed complete.

Sold in pieces, 30 yards long by 1½ yard wide. Price, 45s. each.

B. S. WILLIAMS,
VICTORIA and PARADISE NURSERIES, UPPER HOLLOWAY, LONDON, N.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler with the following improvements - viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought-iron are not liable to crack. They are made of the following sizes: -

Table with 5 columns: High, Wide, Long, To heat of 4-in. Pipe, Price. Rows include sizes like 20 in. high, 18 in. wide, 15 in. long, priced at £ 10 0.

Larger sizes if required. From Mr. CHARLES YOUNG, Nurseries, Balkham Hill, S.W., May 29, 1873.

'Having given your Patent "Double L" Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work.'

PRICE LISTS of HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application. J. JONES and SONS, Iron Merchants, 6, Bankside, South-west, London, S.E. When ordering Boilers please refer to the above advertisement.

HILL and SMITH'S BLACK VARNISH, (Registered Trade Mark).

This VARNISH is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received. Sold in Casks of about 20 gallons each, at 1s. 6d. per gallon at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL. 'Pierrefield Park, June 21, 1876 - Sir, - I have this day forwarded from Chestnut to your address a black varnish cask, to be filled and returned with as good varnish as the last we had, which I candidly admit was the best we ever had. Address Varnish to Pierrefield Park, Chestnut. - I am, Sir, yours respectfully, Wm. Cox.'

'H. & S.'s Varnish has been an article of common use on most of the large estates in the kingdom for upwards of thirty years; and their constantly increasing trade in it, and the numerous Testimonials they receive, stamp it as a truly genuine article. Every cask is legibly marked with their name and Registered Trade mark as above, without which none is genuine. Large Illustrated CATALOGUE of Fencing, Hurdles, Field and Entrance Gates, &c., sent free on application to HILL and SMITH, Brierley Hill Iron Works, Staffordshire; 115, Queen Victoria Street, London, E.C.; and 180, Euchaean Street, Glasgow.

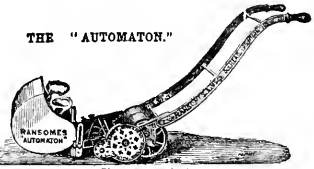

T. MILLINGTON AND CO., 43, Commercial Street, E.

PLATE, SHEET, CROWN GLASS. THE "AUTOMATON"

 Sizes, 8 to 22 inches.
THE BEST GENERAL PURPOSE MACHINE.

The "AUTOMATON" Lawn Mowers are thoroughly strong, well-made, and durable machines, and the best suited for general work and Gardeners' use. They cut the grass perfectly, leave no ribs, but produce a smooth velvety surface on the Lawn, and are light in draught.

The "AUTOMATONS" have front rollers for general work, and *scare* rollers for cutting long grass, or when it is unnecessary to roll the grass in front of the cutters. They have the best machine made gearing, the best self-sharpening knives of steel and iron rolled together, and automatic silent drivers.

R. H. & J. also manufacture
"REVERSIBLE" Lawn Mowers for small Gardens and Borders, and
"HORSE-POWER" Lawn Mowers for Large Lawns, &c.

RANSOMES' LAWN MOWERS ARE THE BEST.
 MELBOURNE EXHIBITION, 1881, THE HIGHEST AWARD.

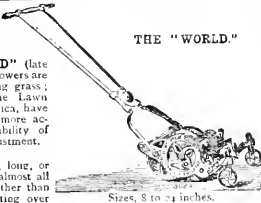

COMPLETE PRICE LISTS FREE BY POST.

Ransomes, Head & Jefferies,
 ORWELL WORKS, IPSWICH.

THE "WORLD" (late "GLOBE") Lawn Mowers are intended for cutting long grass; and, whilst similar to the Lawn Mowers imported from America, have the special advantages of the more accurate fitting and general durability of English manufacture and perfect adjustment.

The "WORLDS" will cut wet, dry, long, or short grass without clogging, and cut off almost all the "beats." They leave the surface smoother than similar machines, and are well adapted for getting over a large amount of work with little labour.

THE "WORLD"

 Sizes, 8 to 24 inches.
FOR CUTTING LONG GRASS.

GREEN'S PATENT "SILENS MESSOR" AND OTHER LAWN-MOWING, ROLLING and COLLECTING MACHINES for 1882.

THE WINNERS OF EVERY PRIZE IN ALL CASES OF COMPETITION.

Patronised by Her Most Gracious Majesty the Queen on many occasions,
His Royal Highness the Prince of Wales,
the King of the Belgians,

the late Emperor of the French, the Emperor of Russia,
and most of the Nobility, Clergy, and Gentry
of the United Kingdom.

Upwards of 105,000 of these Machines have been Sold since they were first introduced in the year 1856,
And Thousands of unsolicited Testimonials have been received testifying to their superiority over all others.

They have been submitted to numerous practical tests in Public Competition, and in all cases have carried off every Prize that has been given.

The following are their advantages over all others:—

- 1st. Simplicity of Construction—every part being easily accessible.
- 2d. They are worked with much greater ease than any other.
- 3d. They are the least liable to get out of order.
- 4th. They make little or no noise in working.
- 5th. They will cut either short or long Grass, wet or dry.

Single-handed Lawn Mower.

To cut 6 inches	Price £1 15 0
Can be worked by a Lady.	
To cut 8 inches	2 10 0
Can be worked by a Lady.	
To cut 10 inches	3 10 0
Can be worked by a strong Youth.	
To cut 12 inches	4 10 0
Can be worked by a Man.	
To cut 14 inches	5 10 0
Can be worked by a Man.	

Double-handed Lawn Mower.

To cut 16 inches	Price £6 10 0
This can be worked by One Man on an even lawn.	
To cut 18 inches	7 10 0
By a Man and Boy.	
To cut 20 inches	8 0 0
By a Man and Boy.	
*To cut 22 inches. By Two Men ...	8 10 0
*To cut 24 inches. By Two Men ...	9 0 0
* It made stronger, suitable for Donkey, 30s. extra.	

Prices of Donkey, Pony, and Horse Machines, including Patent Self or Side Delivery Box, with Cross-stay complete, suitable for attaching to Ordinary Chaise Traces or Gig Harness:—

DONKEY and PONY MACHINES.

To cut 26 inches	£14 0 0
To cut 28 inches	16 0 0
To cut 30 inches	18 0 0
Leather Boots for Donkey	1 0 0
Leather Boots for Pony	1 4 0

HORSE MACHINES.

To cut 30 inches	£22 0 0
To cut 36 inches	26 0 0
To cut 42 inches	30 0 0
To cut 48 inches	34 0 0
Leather Boots for Horse	1 9 0

The 26 and 28 inches can easily be worked by a Donkey, the 30 inches by a Pony, and the larger sizes by a Horse; and as the Machines make little noise in working, the most spirited animal can be employed without fear of it running away, or in any way damaging the Machine.

GREEN'S PATENT "MULTUM IN PARVO" LAWN MOWER.

PRICES.

Without Grassbox.

To cut 6 in.	£1 1 0
To cut 7 in.	1 8 0
To cut 8 in.	1 15 0

This Mower is specially designed to meet an almost universal want experienced by those who have small lawns or grass plots, to have a good and useful machine at a low price. The inventor having seen this want continually increasing, year by year, has brought out the Mower to meet the requirements of the public by supplying a good and useful machine at a cheap rate.

PRICES.

With Grassbox.

To cut 6 in.	£1 5 0
To cut 7 in.	1 13 0
To cut 8 in.	2 0 0

It is simple in construction, easily adjusted, is well adapted for mowing small plots, cutting borders, verges, round flower beds, the edges of walks, &c.; it is a most handy, serviceable machine, and very easy to work.

GREEN'S PATENT GRASS EDGE CLIPPER.

Specially designed to cut the overhanging grass on the edges of walks, borders, flower beds, &c., and to do away with the tedious operation of cutting with shears.

SIZE and PRICE.

Wide ..	Diam. ..	Price ..
8 inch ..	7 inch ..	£1 1

Packing Case, 2s.

GREEN'S PATENT LAWN TENNIS COURT MARKER.

This Machine is of novel design and construction, and the simplest and most effective in its operations.

In the trough containing the liquid there is a loose drum which revolves when the machine is in motion, and conveys the marking material to the intermediate pulley, which in its turn transmits it to the front one, so that the ground is marked effectively as the machine is pushed along.

Price, 21s.

Small Bag of Patent Marking Composition, Mat, and Packing, 1s. 6d.

Delivered, Carriage Free, at all the principal Railway Stations and Shipping Ports in England, Scotland, and Ireland.

No Lawn Mower Manufacturer keeps so large a stock of Mowers as is to be found at our London Establishment, 54 and 55, Blackfriars Road, where purchasers can select out of several hundred Machines, of Hand, Pony, and Horse Power, and have their Orders executed the same day they are received.

The above Machines are Warranted to give entire Satisfaction, otherwise they may be returned AT ONCE, free of cost to the Purchaser.

N.B.—Those who have Lawn Mowers which require repairing should send them to either our Leeds or London Establishment, where they will have prompt attention, as an Efficient Staff of Workmen is kept at both places.

Garden Seats and Chairs, and Horticultural Implements of every description, Wire Netting, &c., &c.

Descriptive Illustrated Price Lists free on application to

THOMAS GREEN & SON (Limited), Smithfield Ironworks, Leeds; and 54 and 55, Blackfriars Road, London.

CHARLES TURNER'S

DESCRPTIVE CATALOGUE OF SEEDS FOR THE GARDEN AND FARM.

Is now ready, and may be had free on application.

THE ROYAL NURSERIES, SLOUGH.

HENDER'S NEW FUCHSIA, EDELWEISS.

In every respect the finest Double White Corolla ever offered.

Flowers large, corolla of the purest white, very double, sepals rich crimson, well reflexed; its floriferousness is unapproached by any other variety...

Testimonials.

From Mr. R. SOWERBY, Gr. to Sir H. Johnston, Bart., Halifax, West. "Edelweiss" is most remarkably good and free-flowering variety...

From Mr. J. HAMMOND, Gr. to Sir W. Alfred Lawson, Bart., Brighton, "Edelweiss" is an extremely free-flowering variety, and I expect it will become popular...

From SHIRLEY HIBBERD, Esq. "Your Fuchsia, 'Edelweiss,' is a grand variety, and well of good value to the owner of the Fuchsia in a land overrun by Goths...

From Mr. KRON The Gardens, Port Elliot, S. Australia. "Having seen your Fuchsia, 'Edelweiss,' as the finest Western Horticultural Society, London, I can say it is the Royal White Fuchsia I have ever seen..."

From Mr. J. HORSHFIELD, Gr. to Lord Helyarbury, Helyarbury, Wilt. "After having seen your new Fuchsia, 'Edelweiss,' a fair trial, I have no hesitation in pronouncing it to be the best double white variety with which I am acquainted..."

From Mr. F. RUTLAND, Gr. to the Duke of Richmond, Richmond, Kent. "Edelweiss" has given me much pleasure in giving your new Fuchsia, 'Edelweiss,' a trial, and I have pleasure in saying it is an excellent variety...

DOUBLE FLORET DAHLIA.

THREE CERTIFICATES OF MERIT Awarded for its 'New Form,' by the following Horticultural Societies:

Royal Western, Plymouth; Devon Botanical, Plymouth; District Horticultural Society, Penzance.

One of the greatest novelties in the 'form' of the Dahlia yet offered. Each floret has another of smaller size within it. Flowers of good outline, colour rich crimson.

To be sent out after the middle of April, 25, each.

Opinions of the Press: HENDER'S DOUBLE FLORET DAHLIA. During the last few weeks I have been visiting some of the exhibitions in South Devon and Cornwall, and none of the novelties have struck me so much as the Dahlia of which the name is given at the head of this note...

NEW ZONAL PELARGONIUM, CRIMSON VESUVIUS.

A magnificent sport from Salomon Vesuvius, with fine crimson flowers. Trusses very large, habit dwarf, equal to the old Vesuvius for floriferousness.

Price 1s. each; 2s. per dozen, Post free. Autumn struck.

Testimonial: Mr. W. PATTERSON, Gr. to Her Majesty The Queen, Balmoral Castle. "Judging from the immense size of the truss of your new Vesuvius, and the colour, I have no doubt but what it is a great improvement on the old Vesuvius..."

HENDER and SONS, NURSERY, PLYMOUTH.

Lawn Mowers. — Lawn Mowers.

THE GREAT SUPERIORITY OF GREEN'S PATENT "SILENS MESSOR" AND OTHER LAWN MOWERS

OVER THE COURSE OF ALL OTHER MAKERS IS UNIVERSELLY ACKNOWLEDGED.

THEY WILL CUT Either Short or Long Grass, Bents, &c., Wet or Dry.

These advantages no other Lawn Mowers possess.

They are the only Mowers which have been in CONSTANT use from 15 to 20 years in the Royal Gardens, Windsor.

- Buckingham Palace Gardens Marlborough House Gardens Royal Horticultural Society's Gardens, South Kensington. The Royal Botanic Gardens, Recent's Park. The City of Palace Company's Gardens, Sydenham. The Winter Palace Gardens, Dublin. And in most of the Principal Parks and Squares in the United Kingdom.

Royal Horticultural Society's Show, South Kensington, London, June 3 to 7, 1881. The following Prizes were awarded to THE GREEN & SON (Limited), Leeds and London: A Silver Medal, the 1st and Highest Prize of the Royal Horticultural Society, was awarded to Green's Patent "Silens Messor" Lawn Mowers.

"The Journal of Horticulture," of June 9, says:—"Messrs. GREEN took the Silver Medal in this class of eight exhibitors, each having a number of machines, was no exception, for special advantages in some form or other were claimed for each kind of mower, and it may be safely said that all were good and did their work well."

"The Garden," of June 11, says:—"Messrs. GREEN took the Silver Medal for their Mowing machines, which were represented by their 'Silens Messor,' and the horse-mower machines with new patent side delivery grass boxes."

They are the simplest in construction, the easiest to work, the least liable to get out of order, make little noise when in use, and are the most durable Lawn Mowers extant.

Table listing mower specifications and prices: To cut 6 inches... 1 s. 0 d.; To cut 8 inches... 1 s. 6 d.; To cut 10 inches... 2 s. 0 d.; To cut 12 inches... 2 s. 6 d.; To cut 14 inches... 3 s. 0 d.; To cut 16 inches... 3 s. 6 d.; To cut 18 inches... 4 s. 0 d.; To cut 20 inches... 4 s. 6 d.; To cut 22 inches... 5 s. 0 d.; To cut 24 inches... 5 s. 6 d.; To cut 26 inches... 6 s. 0 d.; To cut 28 inches... 6 s. 6 d.; To cut 30 inches... 7 s. 0 d.; To cut 32 inches... 7 s. 6 d.; To cut 34 inches... 8 s. 0 d.; To cut 36 inches... 8 s. 6 d.; To cut 38 inches... 9 s. 0 d.; To cut 40 inches... 9 s. 6 d.

Prices of Horse, Pony, and Donkey Machines on application. They can be had of all respectable Ironmongers and Seedsmen in the United Kingdom, or direct from the manufacturers.

Carriage paid to all the Principal Railway Stations in the United Kingdom. Illustrated Price LISTS free on application.

N.B.—Those who have Lawn Mowers to repair will do well to send them either to our Leeds or London Establishments, where they will find prompt attention, as an efficient staff of workmen is kept at both places.

THOMAS GREEN & SON (LIMITED), SMITHFIELD IRONWORKS, LEEDS; And 54 and 55, BLACKFRIARS ROAD, LONDON, E.C.

NOTICE.—SELLING OFF OF NURSERY STOCK.

Great Reduction in Price for Cash Payments.

EWING & CO.,

Having determined to discontinue their Nursery Business at EATON, near NORWICH, and in order to induce a quick Sale of their Stock, offer the following discounts off List Prices, viz.:

- 15 per Cent. for Cash with order, 10 per Cent. for Cash within One Month of date of invoice. 5 per Cent. for Cash within Three Months of date of invoice. After Three Months no discount can be allowed. They hold the following in great quantity and of the finest quality: ROSES—Dwarfs of the best old sorts of Hybrid Perpetuals, Bourbons, Mosses, &c., 9s. to 15s. per dozen, 6s. to 10s. per 100. Dwarfs of Teas and Noisettes, best old kinds, 12s. to 15s. per dozen, 8s. to 10s. per 100. NEW ROSES—French Varieties of 1881 and English of 1880, 24s. per dozen. French Varieties of 1880, 18s. per dozen, 12s. per 100. CURRANTS—Black, good bushes on stems, 3s. to 6s. per dozen, 20s. to 30s. per 100; cheaper by the 1000. NUTS and FILBERTS—Largest and Best Varieties, fine Bushy plants, 6s. to 10s. per dozen, 40s. to 60s. per 100. HERBS of many kinds, 3s. to 6s. per dozen. PLUM (Prunus)—Variegated, common (P. domestica variegata), a very striking and easily grown variegated tree, 2 1/2 to 3 feet, 9s. to 3 1/2 feet, 12s. per 100. ELM—Wych, transplanted, 4 to 6 feet, 8s. to 10s. per 100; 6 to 8 feet, 25s. per 100; 20s. per 100. POPLAR—Black Italian, 6 to 8 feet, 9s. per dozen, 20s. per 100; 10s. per 100; 8 to 10 feet, 5s. per dozen, 30s. per 100; 24s. per 100. WILLOW—Bedford or Huntingdon, 6 to 8 feet, 3s. per dozen; 15s. per 100; 8 to 10 feet, 4s. per dozen, 25s. per 100; 10 to 12 feet, 5s. per dozen, 35s. per 100.

- Cerulean, 6 to 8 feet, 5s. per dozen, 15s. per 100; 8 to 10 feet 4s. per dozen, 25s. per 100; 10 to 12 feet, 6s. per dozen. ASH—(Fraxinus excelsior) atrovires, 3 to 4 feet, 12s. per dozen; 4 to 6 feet, 18s. per dozen; 6 to 8 feet, 22s. per dozen; 8 to 10 feet, 28s. per dozen. spectabilis, an exceedingly fine Ash, which grows with extraordinary vigour, 3 to 4 feet, 6s. per dozen; 4 to 6 feet, 9s. per dozen; 6 to 8 feet, 12s. per dozen; 8 to 10 feet, 15s. per dozen.

- BEECH—Crested-leaved, a very ornamental tree, 4 to 5 feet, 9s. per dozen; 5 to 6 feet, 12s. per dozen; 6 to 8 feet, 24s. per dozen. Cut-leaved, very beautiful, 4 to 5 feet, 12s. per dozen; 5 to 6 feet, 18s. per dozen; 6 to 8 feet, 24s. per dozen; 8 to 10 feet, 32s. per dozen. Fern-leaved, one of the most beautiful small trees grown, 3 to 4 feet, 12s. per dozen; 4 to 5 feet, 18s. per dozen; 5 to 6 feet, 24s. per dozen.

- Purple-leaved, the best dark broad-leaved variety, 3 to 4 feet, 9s. per dozen, 60s. per 100; 4 to 5 feet, 12s. per dozen, 75s. per 100; 5 to 6 feet, 18s. per dozen, 120s. per 100; 6 to 8 feet, 24s. per dozen. Weeping, 4 to 5 feet, 12s. per dozen; 5 to 6 feet, 18s. per dozen; 6 to 8 feet, 24s. per dozen. CHERRY PLUM (Prunus Myrobalana)—Early flowering and very ornamental, standards, 2s. and 2s. 6d. each, 18s. to 24s. per dozen.

- HOSE-CHESTNUT—Extra transplanted, very fine, well-rooted, 10 to 12 feet, 6s. per dozen; 12s. per 100; 10 to 12 feet, 12s. per dozen, 75s. per 100. Scarlet-flowered, 6 to 8 feet, 18s. per dozen; 8 to 10 feet, 24s. per dozen.

- ELM—Variegated, Weeping, fine Standards, 5 to 8 feet in stem, 24s. per dozen. Giant or Huntingdon (macrophylla), 10 to 12 feet, 12s. per dozen, 75s. per 100; 12 to 15 feet, 18s. per dozen. Silver Variegated, 4 to 5 feet, 12s. per dozen; 5 to 6 feet, 18s. per dozen; 6 to 8 feet, 24s. per dozen. Scampston's Weeping, the finest Weeping Elm, fine straight stems and good heads, 10 to 12 feet, 24s. per dozen; 12 to 15 feet, 36s. per dozen.

- MAPLE—Norway (Acer platanoides), 8 to 10 feet, 9s. per dozen, 60s. per 100; 10 to 12 feet, 12s. per dozen. WILLOW—Scarlet Palm, a Willow of extraordinary vigour. The trunk of a 100 ft. tree is sent with 600 order, in winter, and it bears "lamb's tails" in spring of very large size. 4 to 6 feet, 3s. per dozen, 16s. per 100; 6 to 8 feet, 4s. per dozen, 24s. per 100; 8 to 10 feet, 6s. per dozen, 36s. per 100; 10 to 12 feet, 12s. per dozen.

- EUONYMUS—radicans argenteus variegatus, a very useful plant for edges to winter beds, 3 to 4 in., 2s. per doz., 12s. per 100; 4 to 6 in., 3s. per doz., 18s. per 100. ELDER—(Sambucus nigra) variegated: a beautifully variegated plant, which thrives close to the sea; 6s. per dozen, 40s. per 100. cut-leaved—a handsome lacinated form, and like other Elders, extremely useful for ornamental planting close to the sea. 6s. per dozen, 40s. per 100.

A slight extra charge must in most cases be made for packing. Where each plant of 100 or 300 is sent with 600 order, the amount for postage may be forwarded in stamps after despatch of goods. All the above prices are subject to the discounts named at head.

THE GENERAL AUTUMN LIST will be forwarded Gratis and Post-free to all applicants. N.B. Post-office Orders should be made payable to EWING AND CO., at Eaton, near Norwich. Cheques crossed GURNEY AND CO., Norwich.

Trade Terms on application.

SPECIAL NOTICE.

B. S. WILLIAMS

Begs to announce that he will send out the following

NEW PLANTS,

FOR THE FIRST TIME, EARLY IN MAY:—

NEW PLANT CATALOGUE,

Which will be ready next month.

B. S. WILLIAMS,

VICTORIA and PARADISE NURSERIES,
UPPER HOLLOWAY, N.

SUTTONS'

SPECIAL GOLD MEDAL,

MELBOURNE, 1880-81.

PRIZE GRASS SEEDS,

FOR
LAWNS, TENNIS GROUNDS,
AND
CROQUET and CRICKET GROUNDS,
Have been used with the greatest success in the grounds of
The Principal International Exhibitions,
The Principal Cricket and Croquet Grounds,
The Principal Parks, &c.,
IN EUROPE.

"Melbourn, October 22, 1880."
"Sir,—By direction of the Commissioners for the Melbourne International Exhibition I have to request that you will be so good as to convey their best thanks to Messrs. Sutton & Sons, of Reading, for their valuable Lawn Grass Seeds planted in the grounds of the Exhibition during the late winter. The seeds have germinated freely and the lawns are now in splendid condition. Messrs. Sutton & Sons may accept my assurance that the introduction of their Lawn Grass Seeds into this country has been attended with very great success.—I have the honour to be, Sir, your most obedient servant,
(Signed) "GEORGE C. LEVEY, Secretary.
To THE CHIEF CLERK, Melbourne International Exhibition Offices, London."

PRICES:—

SUTTONS' MIXTURE for LAWNS and CROQUET GROUNDS, 3s. 3d. per gallon; 25s. per bush.
SUTTONS' MIXTURE for LAWN TENNIS GROUNDS and BOWLING GREENS, 3s. per gallon; 22s. 6d. per bushel.
SUTTONS' MIXTURE for CRICKET GROUNDS, 2s. 9d. per gallon; 20s. per bushel.

HOW to MAKE and IMPROVE LAWNS, see Suttons' Pamphlet, New and Enlarged Edition, gratis and post-free on application.

SUTTONS' CHOICE FLOWER SEEDS.

FREE BY POST OR RAIL.

SUTTONS' NEW PRIMULA—"RUBY KING."
Deep blood red: perfectly distinct.
First-class Certificate, Royal Horticultural Soc., Jan. 14, 1879.
Price, 5s. per Packet, post-free.
Full particulars may be had, gratis and post-free, on application.

THE

Gardeners' Chronicle.

SATURDAY, MARCH 25, 1882.

TRAVELS OF PLANTS.

(Concluded from p. 366.)

THE wild plants of Peru and Chili were carried by the first explorers of those countries to Spain long before they grew in England or Ireland. Potatoes were in Burgundy in 1560, and in Italy about the same time. In 1584 they were at Youghal, but it was not until thirty years later that they took firm hold of the ground in Ireland on their re-introduction at Youghal by Sir Walter Raleigh. Meanwhile Gerard, the herbalist, received from Sir Francis Drake some tubers, which he planted in his garden at Holborn. In 1663 the Royal Society published rules for the cultivation of the new crop. The Dutch carried the Potato to the Cape, and it passed into India in 1800, and has generally spread over the whole world, being confined in hot countries to the hills.

The Potato recalls the memories of an age of travels and voyages, when Drake sailed westwards with his five ships, singeing the King of Spain's beard on his passage, and re-appearing to be dubbed Sir Francis after having circumnavigated the globe. The nation was at all times extremely curious as to foreign countries, and having become wealthy by means of trade and the growth of wool, it naturally welcomed travelled plants and introduced them in its gardens. In exchange for the Potato and two other plants, Tobacco and Cinchona, America obtained from this hemisphere Sugar, Coffee, and the Cocoa-nut.

A word or two on the Sugar-cane, a plant allied to the Indian Rattan, but in the estimation of schoolboys widely different in flavour—the one being bitter, and the other sweet. We pass over its early travels from its home in China, and notice only its passage into Spain with the Moors, into Madeira and Mexico with the Spaniards, into Brazil with the Portuguese, into Barbadoes and Jamaica with the English colonists in the seventeenth century, and into Bourbon and Mauritius with the French.

The exchange of plants between America and the Old World includes Wheat and Maize, whose typical climates are widely different. It is the habit of Maize to commence its growth suddenly at a gallop in June. Wheat, on the contrary, prefers to advance gradually, and it breaks down with rust and mildew when forced on by an excess of sun, without a sufficient pause between seed time and harvest. Maize has been known to run its course in ninety days, and to reach the threshing floor to the tune of 160 bushels per acre. It is not surprising, therefore, that this prolific grain should have accompanied the colonists of various nations over the whole of America from Chili to the chain of lakes. It was introduced into gardens on this side of the Atlantic within fifty years of the first voyage of Columbus. It entered the Mediterranean by way of Spain, and before the death of Queen Elizabeth and her counsellors—two of whom were noted gardeners. It reached the Levant, where it became an important item in the trade of the Venetians. It

afterwards passed up the Danube to Hungary, and travelling eastward with the merchandise of caravans, it gradually entered the Rice countries, and reached China and Japan. Maize, however, is a native of temperate zones, and Rice of the tropics, consequently there are points where they part company. The latter does not find sufficient warmth in Europe north of the Alps; the former is at home in Ohio, Illinois, and the northern part of Kentucky, but in the Gulf States it finds too much heat. In the hot districts, where Cotton and the Sugar-cane flourish to perfection, it becomes magnificent in stem and leaf, and proportionately deficient in the ear or cob.

We will now take Tea. It has not been a great traveller as a tree, but the leaf ranges wide, and frequently passes twice through the teapot in company with any other small leaves resembling it in size. The first Tea was brought to England in 1666 by Lords Arlington and Ossory, who obtained it from the Dutch East India Company. Its original price was 60s. per pound. Fortune and other authorities describe the *Thea bohea* and *T. viridis* (green Tea) as varieties produced by the influence of age, soil, climate, and cultivation. Souchowg, hyson, &c., are sorts which receive their names according to the time of picking and the age of the leaf and of the wood which bears it. Tea leaves, like grass in process of being made into hay, can only retain their green colour when quickly dried without oxidation of the juices by exposure in damp weather. Artificial green Tea is coloured by the use of indigo, gypsum, and Prussian blue, and being slightly poisonous, it has sometimes been known to "murder sleep."

The Paraguay Tea, so largely used in Brazil and neighbouring countries, is a Holly of restricted habitat, with properties very similar to those of Tea.

The Coffee tree is an indigenous evergreen in Arabia, where the berry remained locally unused till a Muffi of Aden acquired a taste for the beverage produced from it in Persia. In 1554 it was sold at Constantinople, where it had a remarkable effect in emptying the mosques in favour of the *cafés*. The berry travelled westwards in 1615 as an item in the Venetian trade. The *cafés* of Paris and the corresponding shops in London became fashionable at the end of the century.

To the preceding list of plants, which have been distributed by the industrious hands of man, we propose to add a few trees, placing first the Date—a Palm which has travelled from the confines of Asia through the Syrian and African deserts. Some of the finest plantations are those around Medina. Those of Egypt are important.

Two other equally important plants are the Banana and Plantain, tropical fruits which appear to be indigenous both on the Euphrates and the Orinoco. A patch of Bananas yields four or five times as much food as the same breadth of Potatoes, and the tree grows from a sucker, bears fruit in eight months, and sprouts and fruits again in three months. It is, therefore, a convenient tree for the tropics, and has been dispersed over them from the earliest ages. It will be remembered that the Bread Fruit of the Pacific—a tree producing fruit the size of penny loaves, yellow, sweet, and pleasant to the taste—was once set up in opposition to the Banana. The excitement on the subject culminated in London, in the idea of a crop of undiluted bread growing ready baked in a large spreading tree of the Friendly Islands. George III. was accordingly petitioned on the subject, and the *Bounty* was sent out to Otaheite under the command of Lieutenant Bligh, for the purpose of securing some specimens of the important tree. The *Bounty* reached her destination in 1788, and shipped 1500 young trees, which were

destroyed during the mutiny. A few years later Admiral Bligh received a similar commission, and succeeded in conveying the Bread Fruit to the West Indies, where the colonists soon discovered it to be inferior as food to the *foo-foo* of the Plantain, or Banana, while the tree itself is of slow growth.

Other food trees of the tropics are the Cacao, which cannot wander beyond the regions of great atmospheric heat and moisture; and the Dourian, the largest of tree fruits which Mr. Wallace enjoyed in the Malayan Archipelago. For the sake of naming the second largest tree fruit, we mention the Brazil-nut, whose woody fruit holds sometimes a quart of those angular and oily nuts. Circumstances prevent these trees from travelling far, but there are others to be briefly noticed.

The Aspen trembles all through Europe. It may have commenced its curious habit in the Caucasian range, where it is still a prominent tree, but historically it has always been dispersed over Turkey and Russia as far as the Frozen Ocean, and there is nowhere such a trembling of Aspen leaves as in the woods around Moscow, where innumerable seedlings sprang up after the conflagration of 1813. The Aspen is found in the bogs of Denmark at all depths, while the Alder, Birch, and Hazel do not occur below the Oak level. Like the Scotch Fir, therefore, it is one of the primeval trees of Europe. It is also a native of the woods of Invercauld, near Braemar, where it ascends to a height of 1600 feet. It travels into Sutherlandshire, loves moist situations and woods, overhanging the Highland lochs. The margin of Loch Katrine and the islet of the "Lady of the Lake" are its favourite sites.

In the Highlands on the banks of the Dee and the Spay, in the pass of Killiecrankie, and everywhere in England, what tree is so bewitching in its beauty as the Birch of Russian pleasure-grounds, and of Siberian and Icelandic wastes? On the Apennines the Birch begins to grow at about 5000 feet above the level of the sea, in Lapland it ceases at a line 800 feet above the Fir, and 2000 feet below perpetual snow. The Birch is the superlative tree as regards the extent of ground it covers, in Northern Europe, and in the variety of purposes to which it is converted in Lapland, where the natives sit in birchen huts on birchen chairs wearing birchen boots and breeches, with caps and capes of the same material, warming themselves by fires of birchwood charcoal, reading books bound in birch, and eating herrings from a birchen platter, pickled in a birchen cask. Their baskets, boats, harness and utensils are all of Birch—in short, from cradle to coffin the Birch forms the peculiar environment of the Laplander.

That fastigate tree the Lombardy Poplar has been traced from Persia, where it abounds, and from the Himalayas, to the banks of the Po, and thence to the margin of our English streams. About a hundred years ago Lord Rochfort imported from Turin the first cuttings of the Lombardy Poplar, which introduced here the novelty of a pole clothed with foliage.

The Cedar of Lebanon is a modern tree in Europe. The oldest ar, or were, at Chelsea, the tallest at Strathfieldsaye, the largest at Sion House. Lebanon is a wet mountain whose frost and snow equals that of Scotland; consequently the Cedar of Lebanon is adapted to the English climate and affects damp situations such as the banks of the Thames. It likes to dip its roots in running water for the purpose of absorption in dry weather. On dry soils it will be found a dwarf.

The introduction of the Cedar of Lebanon into France was an effort of most interesting devotion on the part of Bernard de Jussieu, who brought it from the Holy Land in 1757, and kept it alive on the voyage by sharing with it the very small quantity of water which he received during a pro-

longed passage. In the absence of a flower-pot Jussieu is said to have planted the Cedar in his hat, and by giving it a moiety of his daily glass of water he succeeded in keeping it alive, and afterwards had the satisfaction of planting it in the Jardin des Plantes at Paris. In 1837, at the age of 100 years, it was cut down, having attained a height of 80 feet.

The Elm, a wayside tree in Germany, a Vine-peg in France, and an ornament of several avenues in Madrid, is a puzzling tree to botanists, the genus being too mixed in character to reproduce itself true from seed. The Wych Elm is our only undisputed native, ripening its seed in our climate—the surest test of a native tree—and extending from the coast villages in Sussex to the haughs of the Teviot and Tweed, and even to the Highlands. All the varieties of the British Elms may be referred to this *Ulmus montana*, and to the old English Elm—*Ulmus campestris*—which has smaller leaves, throws up numerous suckers—not a habit of the Wych Elm—and sometimes displays a trunk of 90 feet long and 15 feet girth. This is a constant tree of avenues and parks in the southern and midland counties, and of hedgerows in the valleys of the Thames and Severn. It is spread over Southern Europe, Western Asia, and Northern Africa, and it has been naturalised in England, where it rarely ripens its seeds, of which, indeed, only a portion ripens in France and Germany. The English Elm was rarely found in Scotland before the Union, and only on sites where it was known to have been introduced. It has been distributed over Ireland in modern times. Evelyn spoke of it as being rarely seen north of Stamford, and as having been imported from Italy by our great benefactors the Romans. Even Philip II. admired the stately form of our tree of lights and shadows, whose open foliage admits the light and produces "the checkered shade," which is the charm of woods. He had sat, perhaps, though not too often, with Mary—

"Under the shady roof
Of branching Elm, star proof,"

and on his return to a more congenial country he transported to the Escorial some English Elms.

Space will not allow us to add to this short selection of travelling plants, and we have therefore omitted the Conifers, which have arrived from the East and West in this age of easy transit in numbers too great for enumeration. The same remark applies to the plants introduced by private firms, and to those collected by Sir J. Hooker and other naturalists. H. E.

New Garden Plants.

NEPENTHES HIRSUTA VAR. GLABRESCENS.

THE *Nepenthes* we now figure (fig. 59) we have received from Glasnevin, and have seen in many other establishments under the name of *Nepenthes zeylanica*, together with a red variety of the same known as *Nepenthes zeylanica rubra*. Although familiar with the plant in cultivation we have long been uncertain as to its correct identification. One thing seems certain, that is, that it has nothing to do with Ceylon, though it may have been conveyed there, and introduced from that island. Sir Joseph Hooker, who has made a special study of these plants, refers it to *N. hirsuta*, a native of Borneo. If so, it differs from native Bornean specimens in being nearly entirely glabrous. It belongs, as will be seen from our illustration, to the section with panicle inflorescence. The following descriptive notes were taken from plants growing in the nurseries of Messrs. Veitch, of Chelsea, Williams, of Holloway, and from specimens kindly forwarded by Mr. Moore, of Glasnevin:—

Nearly glabrous. Stem reddish. Leaves sub-

amplexicaul, broad at the base, lanceolate, with two equidistant nerves on either side of the midrib. Pitchers 5 by 1½ inches, elongate, cylindrical, slightly dilated at the base, reddish, with conspicuous veins, or wholly green, wings deep fringed, mouth ovate, slightly prolonged at the back, surrounded by a greenish-yellow finely-ribbed rim; lid about the size of the mouth, cordate, emarginate, with a simple spur. The small pitchers crowded at the base of the stem are similar, except in size, to the others. Male inflorescence panicle, flower segments ovate ciliate. (Pollen cells compound globose ciliate. *H. G. Smith.*)

and of Baker, the *Lygodium polycarpum* of Desvaux, the *Lygodium Forsteri* of Lowe, the *Lygodictyon Forsteri* of J. Smith, under which name it was recently figured in these pages (figs. 46, 47, p. 339), and the *Lygodictyon Schkuhrii* of J. Smith.

According to the modern idea that the marked differences which occur in the venation of Ferns should be made use of for breaking up into groups of more manageable extent the otherwise vast array of species which come under the more antiquated genera, Mr. John Smith many years ago proposed for the plant now in question the generic name of *Lygo-*

Fulcheri; it differs from the common form of the species in the following particulars, as well as in its bolder and more vigorous habit of growth:—

Pinnæ larger (more than 3 inches long, and nearly 1 inch broad), more regularly tapered from the base to the apex, the base obliquely truncate scarcely at all cordately-rounded, and the apex acute.

Though no doubt specifically identical with *Hydroglossum scandens*, we believe our present subject as above observed, as a more vigorous-growing variety of it than that which has been long occasionally, though rarely, met with in collections. We have never seen the older cultivated form putting on anything like the luxuriant growth and ornamental character assumed by the specimen shown last January, at the meeting of the Royal Horticultural Society, by Mr. Kettle, gardener to H. Egerton Green, Esq., of King's Ford, Colchester, to which a First-class Certificate was worthily awarded for its very effective presentation. In that state, as the woodcut shows, it has not only a distinct and handsome but a very characteristic aspect, and may claim an honourable position amongst decorative and exhibition Ferns. The garden name of *Lygodium Fulcheri*, under which it was exhibited at South Kensington, was given to it provisionally in Mr. Green's garden in compliment to Mr. Fulcher, by whom it was brought from Sydney in 1879—then but a tiny plant, which has since made good progress. Mr. Kettle, who deserves our warmest thanks for developing this new beauty, informs us that the imported plant made a good growth in 1880, but that he unfortunately used it for indoor decoration before the fronds were matured, which damaged it to such an extent that they were all lost. It, however, made another capital growth in 1881, and in this dress it was exhibited last January. A recent examination of the plant, moreover, shows that it promises to throw up strong stems in the coming spring. It was grown in what may be termed a warm greenhouse—a small house used for the cultivation of Maidenhair Ferns. The soil in which it was potted consisted of loam and peat in equal parts. The plant exhibited received no special treatment; nor in fact was there any intention of submitting it to the judgment of the Floral Committee until this course was suggested last autumn by a visitor at King's Ford, who supposed it to be a novelty not in commerce.

The *Lygodiæ* consist of two genera—*Lygodium*, with free veins; and *Hydroglossum*, with reticulated venation. They are very similar in external appearance, but are distinct in habit from all other Ferns in that they produce numerous tall, slender, climbing stems from the crown of the roots. In *H. scandens Fulcheri* the stem or caudex is semiterete and of a pale brown colour, producing short branches, from the apex of which grow a pair of fronds, which vary from 6 to 9 inches long and from 4 to 6 inches broad, and are made up of from four to six pairs, sometimes more, of suberiacous pinnæ, attached by short fusco-hirsute petioles, with which they are articulated. The sterile pinnæ are oblong-lanceolate, 2 to 3 inches long, unequally crenate, the lower ones with the superior base subtruncate or slightly rounded, the upper ones with the base acute. The fertile pinnæ are usually shorter, with the little spikelets of fructification projecting from the marginal teeth. The veins, which are prominent on both surfaces, anastomose in about two series of elongate oblique hexagonous areoles. The figure of *H. scandens* in Schkuhr (t. 139) represents the fertile fronds of that species in their smaller form, with more ovate pinnules, resembling the upper left hand figure in the illustration at p. 331, but the fertile parts of the variety *Fulcheri* do not appear to take this abbreviated form.

The species is a native of the Society, Sandwich, Fiji and other Polynesian Isles, and is also found in East Tropical Australia. As an exhibition plant it would go well with the *Gleichenias*, to which it would form a striking and effective contrast. *T. Moore.*

THE QUEEN AND HER SERVANTS.—The Queen has just caused a memorial stone to be placed over the grave of the late Mr. Andrew Toward, in Whippingham churchyard, Isle of Wight. It bears the following inscription, which was written by Her Majesty:—"To the memory of Andrew Toward, for twenty-nine years the faithful land steward of Queen Victoria and the Prince Consort, by whom he was much esteemed. Born December 21, 1795; died May 7, 1881."

FIG. 59.—*NEPENTHES HIRSAUTA* VAR. *GLABRESCENS*.

HYDROGLOSSUM SCANDENS VAR. *FULCHERI*.

The oldest name for this handsome climbing Fern, called *Hydroglossum scandens* by Presl, is *Ophioglossum scandens* of Forster, and hence we think Presl's modern name, adopted above, should be preferred to others which have been proposed. It is not the original *Ophioglossum scandens* of Linnaeus, which is the plant now known in gardens and by botanists as *Lygodium scandens*, and differs from *Hydroglossum* in its free not reticulated veins, as well as in the form of its fronds. The plant bears many *altiss.* Thus it is the *Hydroglossum polycarpum* of Willdenow, the *Lygodium reticulatum* of Schkuhr

dictyon. The name *Hydroglossum* had, however, long before been applied by Willdenow to a genus equivalent to the *Lygodium* of Swartz, and as this thus superseded name included one of netted-veined species, Presl, in his review of the Schizaceae, to which the plant appertains, retained it for the netted-veined genus, to which it belonged on the ground of priority, and we have accordingly adopted it in the Synopsis of Genera which forms part of our as yet unfinished *Index Filicum*.

The new introduction which has been figured at pp. 339, 331, and which is the subject of the present notice, appears to be a more luxuriant form of *H. scandens*, for which we propose the varietal name of

NEW POTATOS.

I HAVE been able to make up a list of twenty-one apparently *hitherto* new kinds of Potatos, and offered in commerce for the first time this season. Of these I find the Messrs. Sutton & Sons to have no less than six kinds, all, I believe, from that prolific raiser, Mr. Robert Fenn. Our Scotch friends have a fair share of the total, as they offer us five kinds; but America, through an English house, as far as I can learn, offers us only two kinds. With so many new home-raised sorts it is but probable that American kinds—none of which have obtained a generally good reputation for table quality—should be somewhat distanced in the race; and I incline to the belief that Americans will be less grown in the future than they have been in the past.

As usual, the white kidneys are one of the strongest classes, not less than eight being of that section. These are:—Victor: a handsome flattish tuber of medium size, and very early. Duke of Albany: a large kind, the tubers in form very much resembling those of Beauty of Hebron, starts at every eye, and should be a large cropper, and will no doubt turn out fine handsome samples. Both of these are offered by Mr. C. Sharpe, of Sleaford. Cosmopolitan: a large, long, flattish tuber, very handsome; a heavy cropper, and quite early: First-class Certificate, Chiswick, 1881; sent out by Mr. Dean, of Ealing. Cleopatra (Messrs. Carter & Co., Holborn): a handsome broad tuber; should be in its correct form a little arched beneath, and rounder on the upper side—a fine cropper; First-class Certificate at Chiswick, 1881, as Foster's Seedling. Victoria Kidney: seedling from the old Victoria, and much earlier, flattish, and fairly handsome; First-class Certificate at Chiswick, 1881; sent out by Messrs. Oldroyd & Co., Shrewsbury. Queen of the South: described as a fine handsome kind; sent out by Messrs. Kerr & Fotheringham, Dumfries. Ingliston Fluke and Cromwell, both sent out by Messrs. Smith & Co., Aberdeen, are evidently of the fluke breed; long, flattish, the former having prominent eyes, the latter the best looking of the two sorts.

The white rounds are Early Regent, Standard, and Fiftyfold, raised by Mr. Fenn, and sent out by the Messrs. Sutton & Sons, of Reading. The two latter received First-class Certificates at Chiswick last year. The tubers are of good round form and handsome. Early Border, another from the same firm, is well adapted for frames and warm borders, and is a very pretty Potato. Early Cluster was one of the first kinds certificated at Chiswick last year. Its tubers are flattish-round and handsome. It is a very heavy cropper, and is sent out by Mr. Dean. Myatt's Albert Edward is a very promising white round, with a good reputation from the raisers. It was exhibited at the International Potato Show last year, but was not, I believe, grown at Chiswick; sent out by Messrs. Myatt, of Evesham. Premier, a roundish oval-shaped tuber, has a dwarf top, and is very early; should be useful for summer exhibition; sent out by Messrs. Downie & Laird, Edinburgh. Fortyfold White, a Regent-like tuber, deep eyed; sent out by Messrs. Smith, Aberdeen.

Of coloured kidneys one of the finest is Defence; sent out by Messrs. Lee & Sons, Hammersmith. It is long, large, and fairly handsome, purplish-mottled in colour, and very distinct. This has not been grown at Chiswick. Prizetaker, one of Mr. Fenn's, and sent out by the Messrs. Sutton, a large and very handsome pale red kind, tubers shaped much like those of Bountiful; First-class Certificate at Chiswick, 1881. Queen of the Valley (American), sent out by Messrs. Hooper & Co., Covent Garden; large and coarse, skin pink, an enormous cropper; First-class Certificate at Chiswick, 1881.

Coloured rounds are limited to Adirondack (American), flattish round, pale red skin, fairly handsome, heavy cropper—First-class Certificate at Chiswick 1881; and Heading Russet, another of Mr. Fenn's, and occasionally referred to in these pages as Berkshire Rose, also sent out by Messrs. Sutton: it is cerise-red in colour, flattish round, and very handsome. Thus we get eight white kidneys, eight white rounds—an unusual proportion of this section, three coloured kidneys, and two coloured rounds. Out of these I think there will not be found one that is not of good table quality, some altogether first-rate, so that it is evident we are going ahead in the right direction. A. D.

OREGON CONIFERS.—By the courtesy of Messrs. Veitch we have been enabled to examine some specimens recently received by them from Oregon, and of which they have a large stock in cultivation. It is satisfactory to find that, though much yet remains to be cleared up, Coniferous nomenclature is so far fitting down, that there was no doubt as to the correctness of any of the names of the specimens we have examined. A few notes on some of the more important are here appended.

PINUS TUBERCULATA.—The bark on the young shoots is a rich cinnamon colour; the leaves are in threes, 3–4 inches long, faintly saw-toothed, sharply apiculate. The cones, 5 by 3 inches, hang down from the main trunk and branches, to the surface of which they are closely appressed, so that on the side next the trunk the cone is flattened, and the scales are checked on their development, while on the other side the cone is markedly convex, and the scales project as stout, conical, woody prominences. The cones hang for years on the tree without falling or liberating the seeds. The action of a forest fire is apparently not found to cause the cones to open.

TSUGA PATTONIANA (foot of the Three Sisters, G. H. Collier, August, 1881).—Branchlets grey, and much cracked when young, ferruginous and pulverulent. Leaves linear acute, $\frac{3}{4}$ inch long, more or less three-sided, covered with stomata on all sides and with a single resin canal beneath the midrib. Cones erect (?), 2 inches by $\frac{5}{8}$ inch, cylindrical oblong, purplish scales, thin, rounded, at first pubescent. Wing of seed oblong obtuse.

THUYA GIGANTEA, Springfield, Oregon.—This is the plant often grown under the name T. Lobbi in British gardens and very different from the Libocedrus decurrens which sometimes does duty for T. gigantea. The cones are deflexed, cylindrical, oblong, with one or two oblong seeds to each scale, the wing being deeply two-lobed at the top.

ABIES GRANDIS.—The specimens entirely agree with those described and figured from Dr. Engelmann's notes and photographs at p. 179, February 5, 1881, and, indeed, come from river-banks in the neighbourhood of Eugene City, Oregon, the same locality as that from which Dr. Engelmann's specimens were derived. In our illustration the cones are shown as too dark in colour, their real colour when fresh being apple-green; but the dried cones are of a brownish tinge. The leaf-section of the specimens now examined shows a much more prominent midrib than is shown in our figure, which, however, is correct in essential structure. Dr. Engelmann, as we have often mentioned, considers the A. Lowiana or Parsoniana or lasiocarpa as a form of A. concolor; but while acknowledging the greater value of his opinion, we can but express our opinion that in English gardens the plant is much more like a form of A. grandis, and the fruiting specimens grown by Mr. Mackay bear out this view. The true concolor is figured at p. 661, May 21, 1881. A Parsoniana (with its many aliases) is figured at p. 649, May 22, 1880, under the name A. concolor, and A. grandis at pp. 179, 180, February 5, 1881. All three are abundantly distinct for garden purposes.

A. AMABILIS (Sisters, Foley's Cascade).—The specimens (shoots and foliage only) correspond accurately with those figured in the *Gardeners' Chronicle*, and show the blunt leaves on the barren shoots, and the acute leaves on the fertile branches.

A. SUBALPINA also corresponds with the figure as given in the *Gardeners' Chronicle*.

ARBOREUM SEBASTIANUM.—The fourth part of the *Icones* contains beautifully executed illustrations of three species of Pterocarya—P. stenoptera, Spachiana, and fraxinifolia—hardy trees with the general character of the Walnut, but varying in the foliage, and with long, racemes of bony fruits, each provided with two leafy wings, varying in shape in the different species. *Cratogeomys leucophloeos* is a species with greyish bark, destitute of spines, elliptic serrate leaves and oblong reddish fruits. *C. coccinea cordata*, one of the finest of the Thorns, whose large crimson oblong fruits are not only handsome but edible. *Calycanthus floridus*, an old-fashioned plant in English gardens, remarkable for its dull-coloured, fragrant flowers. The variety here figured is said to be harder than the type.

PALMS IN SMALL POTS.

In the growth of this large family of plants for general decorative purposes, it is a common mistake made by many cultivators who are anxious to hasten on the size of their plants to frequently report them. This rule may apply to many plants, but I am quite convinced, in the case of Palms in general, that it can be dispensed with. Not only can they be removed from place to place much easier, but their roots will remain more healthy when somewhat pot-bound, provided abundance of water is supplied them. In the case of kinds grown in a stove temperature, for instance, some may be required for indoor decorations, where they will be in a lower temperature for a while. If these plants should be growing in somewhat large pots in proportion to the size of the plant, the roots will be found to suffer sooner than if kept in smaller pots. This I attribute to the roots not being able to absorb the moisture in the soil so quickly as they ought to do, consequent upon the inaction caused by a lower temperature and the excess of soil to their requirements.

If the roots once become unhealthy in the case of a Palm, they will take some time to come round again; and should the plants when in this case have to be utilised in other than their growing quarters, they will the more quickly suffer, as evidenced by sickly decaying foliage. Palms should at all times be abundantly supplied with water, and occasional stimulants administered. For this latter purpose I find Standen's Gardeners' and Amateurs' Friend one of the very best: a little of it should be sprinkled on the soil and watered in. I once had a case in point of a large specimen of *Stevensonia grandifolia* (*Phœnicophorum sechellarum*) which had become too large for its quarters. It had become much pot-bound, even to cracking its pot, and not being disposed to report it, I sank it into the tank of water over which it had been growing; the water, being at all times warm, suited the plant to the letter. By doing this I kept it some time longer in a vigorous condition.

The soil I find to suit Palms best consists of about equal parts of good fibrous peat and sound turfy loam with plenty of fibre; to this we add a few half-inch bones, or bone-meal, and a liberal supply of silver-sand, giving the pots also a good drainage. In shifting the plants, one size larger pot than the former is in most cases quite sufficient. In the case of those in pots that have reached their limit in size, scarcely too much water can be given. For table plants Palms can be grown sufficiently large for all cases in 48-sized pots. We use many even in 60's, in which size some are extremely useful and pretty.

The following is a good selection of kinds for table plants, viz., *Cocos Weddelliana*, *Geonoma gracilis* and *pumila*, *Chamedorea glaucoflora* and *grammifolia*, *Kentia Forsteriana* and *australis*, *Araucaria*, *area*, *lutescens* and *rubra*; *Euterpe edulis*, *Calamus ciliaris*, *Thrinax elegans*, *Acanthophoenix ciliaris*, and *Phœnix rupicola*. For general decorative purposes, and especially adapted through their thriving so well in small pots, the *Kentias* are invaluable: the deep green colour of their bold foliage always makes them attractive. For light leathery appearance none are better than *Chamedorea glaucoflora* and *Cocos Romanzoffiana*, with slender stems and nice heads of plummy foliage; these are well suited for the decorations of entrance-halls, &c. Of good durable kinds resisting the dry atmosphere of rooms as well or better than any others are *Phœnix tennis* and *reclinata*, also *Seafartha elegans* and *Latania borbonica*. All of the *Demonorops* are also serviceable, but require more care in handling, on account of their spines.

Of insects that are troublesome to Palms the white scale is one of the worst; if not quickly checked, sickly yellow spots will soon be seen. Another some what longer kind of scale of a dull colour will settle down along the midrib of some kinds and cause trouble. Mealy-bug is also troublesome. For all the e-an insecticide of proved efficacy, and about 50 per cent. beyond printed instructions in strength to be used, will soon dislodge them. Red-spider is troublesome at times to those of slender growth, as the *Chamedoreas*, and also to *Thrinax elegans*; as the liberal use of the syringe will check these, and all the more effectively if a bag of soot is constantly kept in the tank from which the water is drawn. In purchasing any fresh stock, it is a good plan to select those with a clean healthy stem, stout in pro-

portion to the size of the plant, and the smaller the pot in proportion to the size of the plant the better for the future well-being of the same. *James Hudson, Gunnersbury House, Acton, W.*

CALADIUM TUBERS.

YOUR correspondent at p. 23, vol. xvii., in giving his opinion on this subject, says, "When the leaves have died down in a natural way" he could keep the tubers without giving them any special attention, provided they were placed in not too low a temperature. In this opinion I beg to concur, as I think he has in the sentence quoted hit the very root and substance of the whole question. The reasons for this opinion are founded on the fact of my having witnessed most of the ways of treatment described by your various correspondents in different establishments in England. The dry, the moist, the cool, and the hot, all obtain and have their supporters and defenders with varying proportions of success. My own pet system used to be of the latter class, much experience having pointed it out as the means whereby the greatest success was attained if "the leaves had died down in a natural way," after being fully developed, and having had sufficient time to store up the necessary amount of starchy matter so important to produce a well-keeping tuber. It is the soft, sappy, and spongy bulbs that are so difficult to keep under any kind of treatment, but the well-ripened ones will also rot if placed in too low a temperature.

In Jamaica these plants thrive remarkably well planted in the open ground where the temperature ranges from 65° to 90° Fahr., with the ground temperature never lower than 65°. They like moderate shade, will not stand wind, and during the growing season are benefited by plenty of moisture. I have known them for weeks—I may say months—at a time without a drop of rain at the resting period, or "when the leaves have died down in a natural way." On the other hand, during the same period I have seen them deluged with rain for weeks. Under both conditions the tubers remained sound, and when raised for the purpose of division, &c., their lower surface presented an appearance similar to a new Potato. There can be no doubt, therefore, that the secret lies in a careful attention to the life history of the plant, especially during the "going to rest" period, when from their untidy appearance they are usually "pushed to the back," "shoved down the stoke-hole," "under the stage—oranywhere, in fact, to get them out of the way"—just at the most important time, when careful attention is required to produce a perfect tuber. Grow in good heat with shade, ripen with a little sun, keep warm during rest, and Caladium growers need never despair of keeping tubers with success. *John Hart, Superintendent, Government Cinchona Plantations, Jamaica.*

FUNGI OF ANTS' NESTS.

THE fungi which occur in tropical countries on ants' nests are for the most part very peculiar, but no fungologist has yet made a special study of them in the countries where they abound. Specimens of one or two species of Podaxon are frequently gathered by botanists, as their size and peculiar appearance at once attract notice, and an esculent Agaric has once been found on them in abundance, while a very singular form, to which the provisional name of *Leninus cartilagineus* was given, was found by Mr. Gardner 4 feet below the surface of the earth on the comb of Termites; and the same botanist also gathered in Ceylon what appears to be a form of the common *Nylaria hypoxylon* on the combs of the white ant, but doubtless many interesting though less attractive forms would reward closer researches. We therefore received with great interest specimens of a minute white fungus sent by Dr. Duthie from Saharunpore, which he found, to use his own phrase, "in some white ant runs about 2 feet below the surface of the ground."

The portions of earthy crust, though extremely fragile, arrived in perfect order, and with a common lens showed little white globules, which had all the appearance of Persoon's *Egerita candida*, and on closer examination it was found that the appearance was not deceptive, as the structure was clearly very much the same with what is figured in the *Notices of British Fungi*, and the form of that fungus, but with the addition of

conidia which show a material difference though not sufficient to constitute a distinct genus. It is to be observed that the figures of *Egerita candida*, including those of Greville and Corda, are altogether unsatisfactory, inasmuch that Corda proposed a genus which he named *Crociosporium* for a plant which is congeneric with Persoon's *Egerita*. This genus was adopted by

FIG. 60.—*EGERITA DUTHIEI*.

Bonerden, and still more lately by Sorokin in a late number of *Strie*, vol. iv., tab. 6, of *Annales de St. Nat.*, where there is an elaborate analysis. We recognise, therefore, three distinct species—*Egerita candida*, Pers., *E. Cordae* (sub *Crociosporium*), and *E. torulosa* (Bon.). It is at once clear on the inspection of the several figures that they are congeneric, and we have now to add a fourth species, of which we give a figure under the name of *E. Duthiei*. The little white globe bodies consist of a compact mass of threads with swollen joints, which are often branched and bear at their upper end one or two globose smooth spines, which according to Mr. Broome's observations, sometimes form little chains; mixed with these

FIG. 61.—*EGERITA DUTHIEI*.

threads and proceeding from them are much more slender threads with oblong joints, the ultimate points falling off, and which therefore must be regarded as conidia. *M. J. B.*

Our figure 60 represents both kind of threads with spores and conidia as observed by the writer of this notice, and fig. 61 sketches of the same as observed by Mr. C. E. Broome.

The Herbaceous Border.

PRIMULA ROSEA.—This brilliantly coloured Primrose is now coming in flower on my rockeries and borders, and of all the early rock Primroses is perhaps the best; *P. denticulata* and its varieties are more vigorous in growth, but their flowers are less hardy and less capable of resisting spring frosts. Like most other Primroses, *P. rosea* does best when treated as a triennial; divided plants are liable to club and to flower badly. Some seed sown as soon as ripe in the spring of 1880 produced me 200 or 300 plants, part of which were planted out on rockeries and borders in the autumn of that year, and flowered sparingly at the end of the following March. Owing, however, to the late frosts they ripened no seed. They are now flowering, with many crowns and flower-stalks each, the vivid crimson-pink of the buds when opening being surpassed in the same colour by no flower I know. A plant lifted in autumn and potted and kept in a cold frame till February, and then brought into the greenhouse to flower, produced twenty-one flower-stalks, having nearly a hundred flowers open at a time. The seed is not enclosed in a capsule, but is loose on the outer surface of the receptacle [This statement requires further explanation. Will our correspondent oblige by sending seed at the right time, Ed.], and requires careful watching if it is intended to collect it. It comes up almost as soon as sown. I have spoken of Primroses as triennial because I find that they mostly arrive at their climax in their second spring flowering, after which the flowers are never so fine or the plants so healthy, however carefully they are divided. *C. Wolley Dod, Edge Hall, Malpas, Cheshire.*

ANEMONES APENNINA AND RANUNCULOIDES.—These two very pretty Anemones are at the time of writing (March 13) in full bloom, and will doubtless continue in flower for another three weeks. They are eminently suited for planting out in groves or near woodland walks; in fact, for such a purpose as this one cannot over-estimate their worth. The celestial blue of *A. apennina*, and the rich golden-yellow of *A. ranunculoides*, together with the common white *A. nemorosa*, have when seen from a distance, and intermixed with each other, quite an enchanting appearance; indeed, for an artist with his pigments and brushes, or for a poet in his most thoughtful moods of meditation and reflection, they would form reasonable subjects not unworthy of their skill and imagination. With some persons, I believe, it is a moot question as to whether *A. apennina* is indigenous in Britain. It certainly is growing wild [naturalised] in a small piece of woodland in the park here, and has been known to grow in the same place for upwards of sixty years—how long previously I have no information at hand; but although this is the case I am not at all prepared to assert that it has not been planted there at some time or other, on the contrary, I am very much inclined to think that it has been, and for this simple reason, it cannot be found growing wild—at least I myself have not met with it—in any of the other woods or plantations in the district. *J. Horsfield, Hestonbury.*

SEMI-DOUBLE AND FULL-DOUBLE DAFFODILS.—We all know the two forms of the common double Daffodil of gardens, one in which the outline of the trumpet is preserved unbroken, the inside being double; the other in which the trumpet expands and mixes its petals in confusion, so as to make a full double flower. I was assured by Mr. Harpur Crewe some years ago that this difference is merely an accident of soil and cultivation and not constant in the same bulbs. I have since found by observation that he is quite right, and that the semi-double is in the common Daffodil the more vigorous form of the two, produced by rich strong soil, and that by transplanting into thin and poor soil the full-double flower is produced. It has several times been stated in the *Gardener's Chronicle* that the double form of the wild Daffodil, *N. pseudo-Narcissus*, generally has the trumpet only double. Last year I received by post from Devonshire a dozen bulbs of it, all in flower, and all semi-double. This year their growth is, as might be expected, rather weak, but nearly all are flowering, the flowers being full double. In the double forms of *N. incomparabilis* I believe that poverty of soil causes the flowers to revert to a nearly single form, as in this gravelly soil I have often found them with only the inside of the cup double. *C. Wolley Dod, Edge Hall, Malpas, March 17.*

Orchid Notes and gleanings.

WORK IN THE HOUSES.—The growing season could hardly have opened in a more favourable manner for all classes of Orchids, and any plants that the grower intended to retard will be more difficult to keep at rest during the next month or six weeks; and, should the present exceptional weather continue, any Cattleyas or Dendrobiums that may be required for late flowering will be perfectly safe if placed in the cool-house for a month or so; and any plants in the East Indian-house that it may be desirable to keep late should be placed in a warm, moist corner of the Cattleya-house, where they should be closely watched, and if the plants show any signs of suffering from the change, remove them at once to their old quarters. Before the next Calendar appears we hope to re-surface all the Phalenopsis, and any that are well rooted and are now large plants for the size of basket they occupy, will be placed, without being disturbed, in baskets a size or two larger. In every case all the old moss will be carefully picked out from the roots of the plants, and as much of the old drainage and charcoal as can be got away without injuring the roots. After this each plant should be thoroughly cleansed at the root with the syringe, using tepid water for the operation. Allow the plants to drain and get a little dry before mossing them up again. It is very necessary to be particular in using none but the best and strongest moss for these plants. In sorting the moss for Phalenopsis we select the growing points of the moss only, which when put round the plants makes a light springy dressing through which the air can permeate freely, and this soon induces the plants to root vigorously. Drain the baskets thoroughly and place a few pieces of charcoal across the top of the baskets, just under the base of the plants. The new roots will soon find out the charcoal and travel along it to the outside of the baskets, where, if the atmospheric conditions of the house are suitable, they will rapidly extend. Avoid keeping the moss soddened about the roots, but the surface should be lightly and carefully syringed to start the moss into growth, and when this takes place the plants generally do well for the season. In the East Indian-house the *Vandas suavis* and *tricolor* will now be flowering freely, and as soon as their flowers are cut the plants should be carefully sponged over to clear them of any exudation from the flowers. In this house the useful winter-flowering *Cypripedium Hookeri* will be in right condition for being repotted, and if the plants are getting large they may with advantage be divided. Pot them in a mixture of two parts fibry peat to one of clean sphagnum moss. *Cypripedium Stonei* in the same house will be making up its growth, and as the flower-spikes will shortly appear it should not be allowed to suffer for the want of water.

Plants of *Odontoglossum citrosatum* that have been grown in the Cattleya-house will now be showing flower, and should be elevated to strengthen their slender spikes. A few plants of this species should always be grown in the cool-house to give a succession of flowers, and though they do not make such fine growths as in the Cattleya-house, we have always found them keep healthy and flower freely in the cooler temperature. In this house the winter-flowering *Oncidium Cavendishii* will now be getting over, and the plants may be started into growth again at once. Repeat any that require it, and start them in the East Indian-house, giving them a light position, and when the foliage is fully formed the plants will bear a considerable amount of sun with advantage. Should easterly or north-easterly winds occur after the bright weather we have had, it will be necessary to ventilate very cautiously; and during the prevalence of winds from these two quarters the houses should always be kept a little moister than when a southern or westerly wind is blowing. J. Roberts, *Gardenshire*.

CATTELEYA TRIANE VAR.—Referring to the note upon the above in last Saturday's issue, of Messrs. Veitch's varieties, permit me to state that one of the most distinct—which was perhaps not there when the

writer of the note referred to walked through the houses (as I purchased it)—is the joint bloom on a last year's imported plant of six bulbs that has made two leads and flowered from one. The bloom is 4 inches across and almost round. Colour uniformly bluish, with two exceptions—1, the venation of the petals is a fainter shade, almost white; and 2, the labellum, which is darker than the rest of the flower, the dark purple front and dark orange throat being divided almost as if painted, so distinct is the division of colour; the margin is crisped and white. The plant-roots are aerial, as yet none holding to anything, and no plant has yet its full strength. Next year I look for a great improvement even on this description. D. B. C.

DISA GRANDIFLORA SEEDLINGS.—I send you a small tuft (fig 62) out of a pan of seedlings of *Disa grandiflora*, to show how freely they are produced from seeds. These were sown on October 31 last. At four weeks after sowing they make their first leaf; they do not make much progress until they are about a year old. When the autumn growth begins they make rapid progress, and at the end of the second year they are strong plants. Some that were sown in the autumn of 1879 have every appearance of flowering during the coming summer. I have crossed *Disa* with many sorts of Orchids, but fertilisation does not seem to be readily effected. However, a cross with *Holca eclectica* as the pollen parent produced five seeds, three of which are growing, but whether a cross was really effected would be hard to say, as a

FIG. 62.—SEEDLING PLANT OF *DISA GRANDIFLORA*.
(The line to the left side indicates the real size.)

grain of pollen might have fallen on the stigma in taking out the pollen masses. T. Myles, *Lambethhurst*.

LÆLIA HARPOPHYLLA.—This distinct species is now in flower in several collections, but I must confess when I saw it in the Burford Lodge collection and also in Mr. Lee's collection at Leatherhead I was disappointed with it. The plants at present in flower were so far behind the fine form exhibited by Sir Trevor Lawrence at South Kensington last spring as to raise the question whether the large-flowered variety, which is probably scarce, should not have a distinctive name. There is a very good form of it in flower in Messrs. Veitch's nursery, King's Road, Chelsea, at present. It has quite the colour of *Lælia chinabarina*, but the flowers have considerably more refinement, and are borne on stems about 6 inches long, the flowers not rising higher than the tops of the leaves. The flowers are very useful to cut for small vases or for buttonhole flowers. I find it succeeds best near the glass in the warm end of the Cattleya-house. J. D.

FRUIT PLANTATIONS.—Gerard, in advocating the planting of fruit trees, alludes to one objection that may be raised to the practice in the following terms: "but Envie saith, the poore will breake downe our hedges, and we shall have the least part of the fruit," but forward, in the name of God, graffe, set, plant, and nourish up trees in every corner of your grounds, the labour is small, the cost is nothing, the commodity is great, your selves shall have plenty, the poore shall have somewhat in time of want to relieve their necessity, and God shall reward your good mindes and diligence."

The Flower Garden.

ROSES.—The completion of the pruning of Roses is now imperative and no time should be lost; the extraordinary mild weather has encouraged a very strong growth which, however, must all be cut back to the dormant eyes at the base: very strong shoots may be left from 4 to 6 inches in length, but the weak ones should be shortened to the lowest dormant bud, and where shoots are very much crowded they should be thinned out. When pruned let the borders be dressed with a good and rich compost of strong loam and dung, which should be carefully forked in but not so deep as to disturb the roots; in the progress of this work we have found that the soil about them is in what we call a rather unkind condition particularly when the drainage is defective owing probably in a measure to the want of the disintegrating influences of frost, the greater reason therefore that it should be at once turned up to the influences of the sun and wind. Care should be taken to make all labels good and to put new stakes to standards where necessary.

SUBTROPICAL PLANTS.—The seedling plants of these will now require to be potted off singly in small pots, and plants from the stores potted some time back, if full of roots, may be treated to a shift; it should be borne in mind that these must all be kept gently on the move in growth, and at the same time a beginning must be made by changing the rooted plants into an intermediate temperature to prepare them for the necessary hardening off—in fact the whole stock of tender plants intended for open air culture will for the next two months be undergoing the various gradations of temperature intended to prevent them receiving a severe check when turned out. Guard against exposing them during the process of hardening to sharp cutting winds, which are often injurious as the weight of foliage increases. Continue to insert cuttings of choice Dahlias and look to the roots of single varieties, potting the weak ones and placing the larger ones in leaf-mould to furnish cuttings or to make strong plants as wanted, the seedlings sown last month as directed will be ready for potting and should have every encouragement to make a strong growth. Golden Feather may still be sown on a slight bottom-heat under glass; they will make nice plants by planting time; earlier sown plants may be potted and brought forward under glass if required large.

ANNUALS.—It will be time next week to commence the main sowings of the different varieties of hardy annuals in patches in the mixed borders; each patch should be marked with a small stick, so that the position may not be disturbed in future planting operations. If a gentle bottom-heat has been secured, the sowing of tender annuals should be made at once. These form a very important part in the autumn display of the flower garden and should have every attention. If sown at once in seed-pans or boxes they will be ready for pricking out into a larger space early next month, and thus a supply of nice stock plants will be secured. *Helichrysum* are amongst the first requiring this attention, as they must be early to ensure a good display of bloom. The double-flowered *Zinnia elegans* also forms a very durable and beautiful bed, and should be sown early and pricked out. *Marigolds* (both French and African), *Tropæolums*, *Dianthus*, *Petunia*, and *Gaillardia* are all showy and necessary, and must be subjected to the same routine. It is time now to plant the beds of *Tigridia pavonia* and *conchiflora*; insert the bulbs 4 inches deep and cover them with sand, keep the beds fairly moist until they are in good growth, when they require a large quantity of water, with liquid-manure occasionally.

ROCKERY.—In the course of the regulating operations in this department care must be taken to use the shears very freely upon all the autumn-flowering hardy Heaths; this will keep them nicely in shape and greatly strengthen the bloom. The white and purple Irish Heaths are peculiarly amenable to this discipline. The hardy fernery should now be thoroughly overhauled and cleared of extraneous matter, and well top-dressed with peat and loam. John Cox, *Keston*.

The Orchard House.

By this time the fruit ought all to be set in the early house, and swelling; if so, and the weather is warm in the day, give the trees a good washing with the syringe or garden-engine between 7 and 8 o'clock in the morning, and as soon as this is done open the ventilators a little at the highest part of the house. If there is any greenly on the trees, there is no more effectual way of destroying them than by fumigating in the evening of calm days. If the trees are in pots, they will now be making fresh roots very freely, and it will be necessary to give plenty of water, examining the soil at intervals to see that it is not overdone. I have often urged the importance of noticing those trees that have been top-dressed, especially if the dressing was applied late in the season; it is so easy to be deceived, because the top-dressing will be quite moist when the part of the soil underneath is quite dry, owing to its being packed full of roots. It requires some experience to know when the trees are all right in this respect. The temperature need not be higher than 55° at night, but if the weather is mild it may be maintained at 60°, with just a little artificial heat. In the house where no artificial heat is applied, the trees are now in flower; and with favourable weather the fruit will be sure to set well. There are frosts every night, but not so severe as to lower the temperature much below 40°. We shut the house up shortly after 4 P.M., if the temperature is low at that time; if it is over 55° we do not shut up until an hour later. Twice a day we go over the trees and gently shake them to distribute the pollen; this is done at 10 A.M. and about 1 P.M. If there are only a few trees, and the owner is much interested in them, he may not think it too much trouble to go over the blossoms once or twice a day with a camel's-hair pencil, using the brush very lightly. Those varieties which are shy setters ought to be crossed with a free setting variety. *J. Douglas, Loxford.*

Grapes and Vineries.

The earliest house can still be kept at a night temperature of 65° to 70° with a rise of 10° by day. The bright weather is very favourable for pushing them on. Close the house early in the afternoon, and with bright sunshine let it run up to 90° with plenty of atmospheric moisture. Now that the stoning process is about completed, look the bunches over for the last time, taking out all stoneless berries, or any that are crowded and likely to bind in the final swelling. Water the borders thoroughly when dry with tepid manure-water, and syringe the borders occasionally with manure-water, the ammonia given out being very beneficial. As the laterals commence to grow, if there is any part of the trellis destitute of foliage, tie them down until all the trellis is covered, and do not stop them any more except to prevent overcrowding. If such kinds as Foster's Seedling or Madresfield Court are grown in the early house, do not stop them at all after the stoning period, as the foliage will to a great extent prevent them from cracking. Admit air early when that the weather is bright, and steadily increase it till mid-day, taking care not to have a rush of cold air, for even with bright sunshine the outer air is at times very cold. The first house of succession Hamburghs will now be thinned, and can be kept as advised in previous Calendars. Those started about February 1 will be coming into flower, and must be kept at a night temperature of 65° with a rise of 10° by day. Take off the surplus bunches before they come into flower, and if the border is dry, water thoroughly with clear tepid water at once, they will not then require any more at the roots until they are set and thinned, when they must have a good soaking. Do all the tying down and stopping a few days before they come into flower, and let the evaporating pans go dry until they are set; damp the house down early in the day, so that it will dry up early, and the atmosphere be light and buoyant towards mid-day. Tap the rods several times daily to disperse the pollen. Keep Muscats that are set at a night temperature of 70°, with a rise of 10° by day; do not thin them until the leading berries can be seen, or the result will be a number of small stoneless berries. After thinning is completed, water the border with manure-water at a temperature of 85°, for it is of the utmost importance that Muscats should always have the water warm.

Keep the evaporating pans filled with weak manure-water, and damp paths and borders with tepid water several times daily. Admit air on the back ventilators early in the day, and close early in the afternoon, to economise fire-heat. Those started about March 1 will now be breaking fast and must be kept at a night temperature of 60°, steadily increasing it as growth advances, with a rise of 10° by day. Any strong young Vines that have been tied down to induce them to break regularly must be tied up to the wires before growth is far advanced. I usually tie the main stems a few inches below the wires, so that when they are in flower and the rods are shaken the pollen disperses better. All late varieties, such as *Alicante*, *Gros Colmar*, *Lady Downe's*, &c., for keeping through the winter, if started as previously recommended, can be kept at a night temperature of 60°, with a rise of 10° by day; let the temperature rise to 80° with sun-heat at closing time, as it saves fire and is more healthy than fire-heat. Keep the rods well syringed several times daily until the bunches can be seen, when it may be discontinued. Keep the paths and borders damped down with tepid water several times daily according to the state of the weather outside. Early pot Vines must have liberal supplies of tepid manure-water, for unlike established Vines they have only very limited root-space, and ought to be looked over twice daily, for if they once become thoroughly dry at this stage they never recover it; keep a moist healthy growing atmosphere, and close early in the afternoon. If wanted as early as possible they may this mild weather be kept at a night temperature of 70°, with a rise of 10° by day. *Joshua Atkins, Lockinge Gardens, Wantage.*

The Hardy Fruit Garden.

THE bright weather we are now experiencing is exerting its influence on the buds of all fruit trees; especially is this the case on walls, where such early blooming fruits as Apricots and Peaches form quite a beautiful show. Every available means for the protection of this excellent promise should be utilised in assisting to prevent that rapid radiation of heat from the walls which occurs under unclouded skies during the nights of such fine days as we are now enjoying, when the thermometer hovers about the freezing-point each morning. Amongst the best of helps in this direction may be mentioned temporary coping boards to which the protecting material can readily be attached. It is well to see that this material be either removed on fine days, or be of so open a description that a free circulation of air passes at all times. Even such seemingly slight protection as is afforded by a single or doubled herring-net has great influence in limiting the loss of heat from walls; and, if supplemented by thicker covering on emergencies, when we have relapses of almost wintry weather, will be found of great practical utility. Upright boards placed against walls at convenient intervals are also of great use in breaking the force of winds in situations where the trees are much exposed, and such boards may be retained for some time after the ordinary protecting materials have been removed, and until the foliage has become sufficiently firm in texture to resist the sudden chills that are so productive of blight on Peaches. The covering may now be removed from Fig trees, but it will be well to do so by degrees, or at least to provide some slight covering to use if the state of the weather should make it advisable to again protect for a time. Where the pruning has been deferred until the uncovering of the trees at this time, it will be necessary to proceed with it without delay; as, although it is of advantage to be able to see exactly which shoots are best furnished with embryo Figs, late pruning is apt to induce bleeding when put off too long. Thin out the branches where over-crowded; cut back those of the bearing-shoots of last year that are not required for the extension of the tree, also any weak, unproductive growths, and remove entirely any gross shoots that are not wanted to furnish any part of the tree. In rearranging the branches on the wall see that they are securely fastened with tying material of a sufficiently strong description to support their massive foliage, and to resist the great pressure of wind to which their large leaves expose them.

Let all grafting that remains to be done be proceeded with at once, and see to the moistening of the

clay of grafts put on in the beginning of the month. Ugly gaps are occasionally seen in otherwise well-furnished Pear trees on walls; such vacancies can be effectually filled by inserting ring grafts, which may be put in by lifting the bark with a T cut as in budding, but with the cut across made as a notch, removing a portion of bark to facilitate the insertion of the scion. This is also a ready means of testing new varieties, which can thus be speedily fruited where there are strong and established trees to work upon. For those interesting themselves in raising seedling Pears, this means of propagation offers more speedy satisfaction than working upon independent stocks would be.

Fruit trees carrying a heavy bloom will be greatly assisted over the exhausting process of perfecting such quantities of pollen by being supplied with liquid manure where such is obtainable, but it will be well to bear in mind that, if applied while the blossom is open, it ought to be done in the early part of the day, so as not to lower the local temperature about the tree at night by evaporation; and at present we are happily having a dry time, which, if continuous over the blooming period, will greatly enhance the prospects of a full fruit crop for 1882. *Ralph Crossling, Castle Gardens, St. Fagan's.*

The Pine Stove.

SHADING should be applied over the glass without delay: in light structures it is absolutely necessary. Too much, however, is as injurious as too little, therefore the proper medium should be arrived at. What is requisite is a means of shading that does not intercept the light, and at the same time regulates the solar heat. The sun's rays become chemically changed in their passage through the glass, therefore when it becomes too strong its effects should be diminished. Most growers are aware that the largest fruits of the season are those ripened in the autumn, which can only be attributed to the fact that the heat and the sun's rays are more equable. An ordinary observer will soon notice the difference in the colour of those grown in the shade and others grown in the sun; the former have a colour and freshness that the latter never attain. Successful shading is a vital point in culture, and this is why we allude to it so comprehensively. There are many different ways of shading as well as different modes of ventilation, which look light and elegant, but which in working are complicated, and soon get out of order. The system we adopt and like best is a roller with a wheel at its end; this folds and unfolds the cords as the rollers are worked up and down the roofs. If the houses are in one long continuous roof the rollers can be worked by two rollers pulled up and down from each end; two rollers worked in this wise will shade a roof from 120 feet to 160 feet long. When the shadings are let down the rollers run from the apex to the bottom of the roof, and when adjusted the opposite motion takes place. At the top of the roof is a piece of flat wood 2 inches broad and about 1 inch thick: this is the length of the shading. The canvas is tacked to the wood, then the wood is fastened by means of screws to the top of the roof; this holds the scrim fast and in position. Instead of pulling the shading up and down by hand a small wheel is fixed to the end of the house, which collects the cords, and works the rollers up and down more evenly. On one side of the winding-wheel is a cog with a catch to drop into it: this holds the shading at any part of the roof. The scrims used should not be too thick, as this darkens the inside of the house. That unique variety, the Smooth Cayenne, is the most tender and impatient to bright sunshine of all Pines, and it is useless to attempt to grow it without some shading. The varieties of Queens will stand more sunshine than many other varieties, yet Queens must have proper shading. Pines should not be allowed to become too browned, as it creates a state of things not conducive to vigour. The Smooth Cayenne is the first to show unmistakable signs of things not suitable, by having a waxy, brownish appearance, which relaxes the energies of the plants. At one time this, in our own appearance was thought to imply great vigour, but we find the most robust and healthy plants soon assume this colour if exposed to excessive sunshine. *D. Wilson, Castle Hill, Devon.*

PERKINS' CHAMPION BROCCOLI. — We send you half a dozen average-sized heads of our Champion Broccoli, which we are now cutting for the market. The growth is dwarf and compact, and we have seen cutting for three weeks or more, and we have seen cuts of an size and very true. *Thomas Perkins & Sons, Northampton.* [A fine sample of a good close protecting Broccoli. E.]

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	Mar. 27	Sale of <i>Lilium auratum</i> Bulbs, at Stevens' Rooms.
TUESDAY,	Mar. 28	Royal Horticultural Society: Meeting of Fruit and Floral Committees, at 4 P.M.; Scientific Committee, at 4 P.M. Spring Show.
WEDNESDAY,	Mar. 29	Spring Flower Show at Sevenoaks. Royal Botanic Society's First Spring Show, Sale of Established Orchids, at Stevens' Rooms.
THURSDAY,	Mar. 30	Sale of Imported and Established Orchids, at Stevens' Rooms.
FRIDAY,	April 1	Sale of Hardy Plants and Bulbs, at Stevens' Rooms.

MR. DARWIN, whose patient industry is not less remarkable than his candour and his sagacity, has contributed to the Linnean Society another of those memoirs which form such important contributions to the history of natural science. The present case turns principally upon points in the CHEMICAL DEPARTMENT OF VEGETABLE PHYSIOLOGY, and if the results obtained are less conclusive than is the case with some of his previous essays, that circumstance is attributable mainly to the little insight we have at present as to what really goes on in the laboratory of the living plant. The chemist can tell us with much minuteness and circumstantiality of detail the results of his observations and analysis of the dead plant, but the nature of the changes which take place in the living plant in its various stages of growth is a much more difficult problem. Obscure and difficult though it be it is obviously of cardinal importance, not only from the point of view of abstract science, but from the standpoint of the cultivator who seeks for intelligible principles on which to base his operations. The microscopist, too, is able to tell us much of the structure of the machine, but heretofore he has been puzzled to account for the apparent anomaly of seeming identity of structure, and very diverse physiological action. Two cells, mere bags of membrane, enclosing semi-fluid contents, in juxtaposition it may be, and to the eye identical, are often proved by chemical and other means to have very diverse qualities. Such cases are matters of everyday experience, and Mr. DARWIN'S paper will be hailed as a contribution towards its future explanation, furnishing, as it does, another proof of the frequent relative independence of cells, and their differences one from another.

In the present instance Mr. DARWIN'S researches turn upon the action of solutions of carbonate of ammonia on the contents of the cells. Roots of a species of *Euphorbia* were immersed in a weak ammoniacal solution for a short time, and then microscopically examined, with the result that certain of the cells in the immediate vicinity of the tip of the root were found, under the influence of the solution, to be filled with fine brown granules. The course of the ammoniacal fluid upwards, from cell to cell, was traced by this gradual deposition of granular matter from below upwards. It was observed also, that while certain of the cells were thus affected in more or less longitudinal series, adjacent lines of cells, structurally not different, were yet unaffected, so that a kind of alternation existed between rows of cells containing the deposit or precipitate and other rows free from it. A similar functional diversity in different lines of cells is familiar to all who have experimented with coloured fluids or chemical solutions in endeavouring to trace the course of the fluids in question in the interior of the plant. Those cells from which the root hairs originate were, as a rule, free from deposit, thus inferentially confirming the opinion that those organs are organs of absorption rather than of elaboration. Various other solutions besides the ammonia produced similar effects, varying in degree in various cases. That the precipitation was a vital one was shown by experiments with dead tissues of the same plants in which no such effect was produced. Chemical investigation of the granular matter

goes to show that it is of nitrogenous nature, allied to protein.

It would be unlike Mr. DARWIN to confine himself to one plant or one set of experiments, consequently we find that he submitted to like experiment a large number of plants belonging to different families and genera, the details of which we cannot now enter into. It must suffice to say that, with few exceptions, the results were uniform in kind, if not in degree. One exception is remarkable, though its significance is not yet apparent. In the roots of *Cyclamen* the colour of the deposit was green, and it was found in the cells from which the root-hairs spring as well as in the others. The deposit is usually granular, but passes by degrees into globular masses, which become confluent into irregular masses, generally brownish in colour, but sometimes pale blue or green. Alcohol, ether, iodine, or acetic acid have no effect on the deposit, save perhaps to alter its colour, but caustic potash slowly dissolves them. While some plants are conspicuously changed by the ammonia salts, or by osmic acid, and others only slightly so, some are not affected at all. In considering the significance of these changes Mr. DARWIN apparently leans to the view that the substance deposited is something useless to the nutrition of the plant, of an excrementitious character in fact. But on these and other points we can offer no opinion till the publication of the paper, when all the facts of the case will be before us. No doubt it will stimulate further research into those processes going on in the living plant, upon which at present we so greatly need enlightenment.

THE long-expected crisis in the affairs of THE ROYAL HORTICULTURAL SOCIETY has come at last, and was determined by the judgment on Wednesday of the Justices of the High Court of Appeal. It will be remembered that the Commissioners of the Exhibition of 1851, who are the landlords of the gardens at South Kensington, sought to obtain re-possession of their property on the grounds of non-fulfilment of contract on the part of the Society. This action of the Commissioners was resisted by the Society on various grounds, one being that, if the Society ceded the property occupied by them, the interests of the debenture-holders, who lent their money on the security of the property, would be seriously impaired or cancelled. There were incidental questions as to whether the Society and the Commissioners were or were not partners in the matter. If partners, then, of course, the Commissioners must bear their share in the ill-fortune that had befallen the Society, and bear their share of responsibility towards the debenture-holders. When the action came, some months ago, before Mr. Justice FRY, that learned Judge gave his verdict against the Commissioners and in favour of the Society. The verdict occasioned some surprise to those conversant with the history of the affair, and at any rate justified the Society in the action they took. The Commissioners, however, were not satisfied with the decision and appealed against it. The result of the appeal, which is, we presume, final, is to reverse Mr. Justice FRY'S decision, and to enjoin the Society to give up possession of the Kensington Gardens within four months. The debenture-holders, it is affirmed, have no case, and have to bear their share of the costs. Such in brief is the present state of affairs. We do not care to go back into the past history of this melancholy and most involved business. The present judgment relieves us of all necessity for going back to that entanglement. We prefer to consider what may be the probable results of the decision, and if we are correct in our view the results are upon which the Society may be congratulated. Its debenture debt will be wiped off, for, as was pointed out by the Lords Justices, the debenture-holders

lose their money without remedy against any one. If the Kensington Gardens have to be given up the debenture debt, if we are correct in our view, will be cancelled, and no horticulturist will feel much regret so long as it is possible to develop Chiswick, which is not affected by the present decision, and retain a place in London for official business and the holding of exhibitions. It is to be hoped that the Commissioners and the Society will now come to some businesslike and equitable arrangement by virtue of which the Society may retain so much of the Kensington garden as may be necessary for their purposes, be relieved from the incubus of debenture debt, and from the possession of a garden which has become a burden and an eyesore, or, if it be deemed desirable to retain the use of the whole of it, that the Commissioners may find some of the funds necessary for the purpose, so that it may be kept up in a proper manner. We must admit, however, that the functions of a horticultural society are, or should be, of a higher and more practically useful character than the maintenance of a playground for the fashionable residents and visitors to South Kensington, and that by attending to its own proper business the Society is more likely to win in public estimation than by becoming managers of a public recreation ground. These matters, however, depend essentially upon financial considerations, and with the example of the Zoological Society—Jumboism apart—before them, it is clearly not impossible for a society to combine the requirements of popular recreation with educational aims and the demands of advanced science.

—PROLIFEROUS PINE.—Last week we gave an illustration of a Pine-apple in which the pips were replaced by tufts of leaves, miniature suckers, which gave the plant a very noble appearance, even if it were not such as would satisfy the caterer for a civic banquet. We now supply a corresponding illustration (fig. 63), in which the supernumerary growths show themselves in the form of fruits. The fruit of a Pine-apple consists of the whole inflorescence, consisting of many flowers and fruits consolidated into one succulent mass after the fertilisation of the flower, so that what we speak of in ordinary terms as a fruit is in this case really an agglomeration of many fruits and bracts. In the case before us not only is the central spike so changed, but the ordinarily leafy "gills" have undergone a similar change, producing an appearance as striking as in the former case, and one more attractive to the fruit grower, as it gives promise of greater usefulness. We must admit, however, that for table purposes we should prefer one of a less prolific character.

—MR. JOHN LEE.—On Thursday evening, Mr. JOHN LEE, so long and so honourably connected with the Royal Vineyard Nursery, Hammersmith, was entertained at a Complimentary Dinner at "SIMPSON'S." The chair was taken by HERBERT J. ADAMS, Esq., one of the Vice-presidents of the Gardeners' Royal Benevolent Institution, who had the pleasure also of presenting Mr. LEE with a service of plate, of the value of fifty guineas, subscribed for by the office-bearers of the Institution—from the President, the Duke of Buccleuch, down to the Secretary—to mark their sense of the valuable services he has rendered to the Institution during the long period of forty-one years, as a Trustee of the funded property of the Institution, and for nearly the whole of the time as Chairman of the Committee.

—A NEW BALSAM.—In the No. 8 house at Kew is a fine plant of a remarkably handsome Impatiens, of which a figure has been prepared for the *Botanical Magazine*. It came up at Kew among some soil which had been used for packing purposes at Zanzibar. It forms a neat pyramidal bush, has light green foliage and flowers, with long slender spurs and flat corollas of a bright rose-crimson colour, exhibiting in sunlight a marked iridescent gloss. This species, it is to be hoped, will long remain an inmate of our stoves, and not after a year or two quite disappear from cultivation. With the exception of *I. Jerdoniae*, which so many people cannot manage, and which perhaps owes its existence still among us more by reason of its being perennial than on account of its strikingly coloured flowers—a mixture of green, red, and yellow—how few of the tropical Balsam

which have found their way to this country within the last half century, many of them eminently handsome and desirable plants, are at the present moment to be found in British gardens!

— *BEGONIA UNULATA* AS A BASKET PLANT.—In Messrs. LAING & CO.'s nursery at Stanstead Park, Forest Hill, there is now one of the most unique specimens of this Begonia, sometimes called Count Alfred de Leinengen, growing in a basket

baskets who have a plant stove or intermediate-house at command, need have no fear of growing a specimen equally good in a few months from a rooted plant.

— *ENKANTHUS JAPONICUS*.—This is a very desirable shrub, both on account of the profusion in which its white flowers (about the size of those of Lily of the Valley) are produced, and also by reason of the gorgeous colouring assumed by its leaves in autumn. It is, moreover, a compact, neat-habited

of *Cupressus Lawsoniana*. The habit of growth of different individuals is tall or short, compact or loose, pyramidal, columnar, or fastigiate, the branches spread horizontally, or ascend or hang down; they are flattened from above downwards, or from side to side, they are convex or flat, or they are rounded like whip-cord. They are of every shade of green, or variegated with yellow or white. All these variations, and many more that might be cited, occur in one species. It is no wonder, then, that considerable dif-

FIG. 63.—A PROLIFEROUS PINE-APPLE. (SEE P. 404.)

scarcely 12 inches in diameter, and less than 6 inches in depth. There is fully 3 feet in width of its beautifully cut foliage, studded with flowers, and the length of the shoots falling balloon-shape to a point is close upon 6 feet. The plant is now making fresh growth, and the points of the young shoots are projecting in a natural way a couple of inches beyond the clusters of flowers which nestle among the older leaves, and altogether it is perhaps one of the finest basket plants ever seen. A plant that will attain to such dimensions in such a meagre root-run can hardly be said to be difficult to grow, and lovers of plants for hanging

bush, and as it is hardy in Northern France there can be no reason to doubt its suitability for outdoor cultivation in this climate. The Kew plant, which is now in full bloom in the winter garden, was figured in the *Botanical Magazine*, tab. 5822. The flowers last some time, and open before the leaves are fully developed. In autumn the foliage turns to a brilliant golden-orange colour, diversified with redder spots.

— SPECIES.—Any one wishing to form an idea of the little value of "habit" as a means of distinguishing so-called species, should examine a seed-bed

ferences of opinion arise among naturalists as to the limitations, or even the existence of species. Very rarely can the observer have before him all the material requisite to form an absolutely accurate opinion.

— THE WARD JACKSON PARK, HARTLEPOOL.—A premium of £30 is offered by the West Hartlepool Improvement Commissioners for the most approved plan for laying out the new "Ward Jackson Park," 17 acres in extent. A comprehensive and complete design is required for utilising the land for this purpose, but not necessarily for completing the whole at

once, but so providing that the work may be carried out from time to time as may be considered advisable. A lithographed plan of the ground, with sections and all further particulars, may be obtained on application to Mr. GEORGE SCOTT, Town Surveyor, at the Athenæum, West Hartlepool. Each plan must bear some distinguishing name, mark, or motto. All plans must be delivered on or before May 1. We note that a premium is also offered for a design for the laying out of the People's Park at Grimsby.

— **FRUIT BLOOM.**—The ensuing fruit season promises to be one of the best for Pears we have long known, for the bloom will be truly wonderful, and the buds are strong and apparently healthy. At Chiswick the trees, even ere a bloom is expanded, are in almost every case a mass of buds, and when in a week or two hence the blossoms have opened, the gardens will be white almost as snow. True pomologists, who do not limit their observations to fruit only, but note all the characteristics of bud, bloom, and leaf, will find the present spring a remarkably valuable one for observation. Easter Beurré is the earliest expanded kind, and is, indeed, almost a sheet of bloom before a single flower is open upon any other tree. Still farther, although the clear, bright, cool nights have brought several white frosts, not a thickened pistil is yet to be seen. We ought also to have a grand Apricot year. The bloom has been very abundant, and fruit is set in enormous quantities. If no casualties happen there will be ample employment presently in thinning. Peaches and Nectarines are flowering profusely, and the great heat experienced, with dews at night and an absence of east winds, is inducing the fruit to set rapidly. The work of fertilisation is immensely helped by the insects—bees especially, for these are as busy as if it were May. Apple buds are not yet so prominent, but as they develop it is evident that these will be ample, though probably the fruit crop may not be so large as it was last year. Plums promise well; and, indeed, it may be added that the Black Thorn will soon be literally smothered in blossom. We got fair Plum crops last year, but they were partial. Whatever may result, it seems probable that bloom will not be wanting. Cherries are a mass of bloom-buds, but then they seldom fail to flower freely. Of bush fruits there is ample evidence that they will bloom abundantly, but good crops on these is the rule. By no means an unimportant feature is the vast amount of bloom found on many deciduous forest and other ornamental trees, all tending to the promise of a fruitful year.

— **AUSTRALIAN FLOWERS.**—Those who admire natural yet artistically treated representations of flowers, would do well to see a screen now exhibited in the South Court of the South Kensington Museum. It is the work of Mrs. ROWAN, some of whose productions we have had occasion to admire on former occasions. The screen consists of three panels, each of which is devoted to characteristic illustrations of the flora of New South Wales, Victoria, West Australia, and New Zealand. The general scheme is a representation of some characteristic plant, such as *Tecoma jasminoides*, *Kennedyia nigricans*, *Clematis indivisa*, &c., with an undergrowth of *Grevilleas*, *Cephalotus*, *Rhipogonum*, *Acacias*, *Leptospermum*, &c., according to the country. There is a graceful freedom of treatment combined with accuracy of detail and harmonious grouping which is very noteworthy.

— **HELIOTROPE WHITE LADY.**—This is found to be a most useful variety by bouquetists and others who have to form combinations in cut flowers. "It stands well," is the remark made concerning it, and it is all the more noticeable that it is so, as *Heliotropes* have the reputation of soon fading when in a cut state. Not only are the individual flowers larger, but they are produced with great freedom, and by the aid of some heat during the winter flowers can be had almost all the year round. President Garfield, a new introduction of MESSRS. CANNELLS, with flowers of a pale lavender colour, is a decided acquisition also, the individual flowers, as in the case of White Lady, being very fine. The addition of these two fine varieties will no doubt have the effect of calling attention to the undoubted claims of the "Cherry Pie" to a wider recognition than it has received of late. It is a plant that has undoubtedly fallen somewhat into neglect, and yet for cutting purposes the

gardener has scarcely a more useful subject. Sentation, bluish-purple; Swanley Giant, rosy-lavender; Jersey Beauty, bright mauve-purple; and the Queen, creamy-white, are all good varieties for pot culture.

— **BUCKLANDIA POPULNEA.**—A very striking effect is produced in one of the octagons of the Temperate-house at Kew, by the placing on the shelves at intervals of good-sized plants of *Bucklandia populnea*, which rise above the lower growing plants like so many giant sentries. The large leathery pale green leaves of this plant are cordate, ovate acute on long stalks, and are effective by their very simplicity of form. The large reddish stipules of this plant are very curious, consisting of two leafy oblong plates placed face to face in an erect position between the leaf-stalk and the stem.

— **THE ROCK GARDEN AT KEW.**—Extensive preparations are being made for this. The site chosen is near the old Museum No. 2, in proximity to the herbaceous ground, between it and the Orchard-house. The plan adopted is that of a serpentine valley, with undulating banks. The subsoil is almost pure sand, but preparations are being made for a full supply of water. At present, of course, nothing can be seen save the ground-work, the curves of which are very agreeable.

— **COPROSMA LUCIDUM.**—One of the most conspicuous ornaments of the Temperate-house at Kew just now is a large shrub of this species. Its bright shining foliage and profusion of small transparent orange berries are very attractive. The flowers are greenish, and not very showy, but the plant has the advantage of being ornamental for the greater part of the year.

— **RHODIENDRON BUDS.**—The leaf-buds and flower-buds of some of the Sikkim *Rhododendrons* at this season are, as is well-known, almost as handsome as the flowers, and in point of colour sometimes even brighter. What object can be served by this brilliancy before the flowers open it is not easy to guess.

— **THE ROOT TRADE.**—The term "root" is applied so widely that it may be at once needful to say that the root trade to which we refer is neither that of Mangels, Potatos, or other edible products, but is limited in its application in this case to the traffic in hardy flower roots, of which such immense quantities are grown near and around the metropolis. The humble hardy flowers—Daisies, Pansies, Pinks, single Carnations, and many other things—are peculiarly useful to the hawker and ordinary plant coster—an active and enterprising body, who buy up large quantities of things at low prices and dispose of them somehow and somewhere, but always at a good profit; yet it is rather remarkable that although we have had such an open favourable winter for planting of all kinds the root trade has not been active, and prices now are very low in consequence. Perhaps the hawker is, in his dealings with the general public, not his own friend. The anxiety to "get on" at the moment is perhaps natural with a race that evinces little thought for the morrow, but the usual result of the deal is that the customer fights shy in the future of the class of people who have deceived him. The "Jack" trade, as we have often shown, is one of the most unflinishing deceits, yet it flourishes, because it is not limited to the metropolitan suburbs, but has its best market in the provinces, the hawker rarely traversing the same ground twice. In some things deception is not possible, but then the production is so easy that it would be profitless. Hollyhocks, Delphiniums, single Rockets, and some other things are often made to pass for named kinds or good double strains; but Daisies, Pansies, Violets, and other freely propagated plants are generally sold when in bloom. Buyers will find now they can get plants not only cheap but also extra good, as the open winter has promoted growth of an unusual kind, and all kinds are robust and will give ample bloom.

— **POTATO EXPORTS.**—Having regard to the hitherto almost invariable nature and extent of our food imports from the United States, it comes as a surprise to learn that during the past winter a quarter of a million of sacks of Potatos have been sent to that country, and these largely from the United Kingdom. That the vast expanse of land under cultivation in America should have failed to

produce last year enough of Potatos to satisfy the needs of its population is, indeed, a remarkable fact, and one due, it would appear, not to the Colorado beetle, once the threatened scourge of the Solanum in the States, nor to the Peronospora, the chief scourge of our Potato crops at home, but almost solely to drought, which proved so protracted and so universal. With such a wealth of resources, the Americans have not hitherto realised the possibility of home famines of any sort, and therefore have not found, as at home with our vast population and our very limited area of earth have, that restrictions upon the trade in articles of food must be removed, and the widest liberty given to their introduction. When we have had to endure losses incidental to short Potato crops, we have thrown open our market to the world, and the teeming populations have obtained from France, Holland, and Germany ample and cheap supplies. To feed the masses well and cheaply is of more importance than the establishment of some fiscal regulation that looks philosophically right, but is economically wrong. Now that the population of the United States feel, as far as Potatos are concerned, the pinch of hunger, they find the vicious ogle of Protection doubling to them the price of the healthful food, for 25s. duty per ton is exacted upon all that is imported. Our home merchants tell us that but for that intolerable impost the exports of Potatos from Europe might have been doubled. But if it is strange that America should need Potatos from us it is not less remarkable that we should have even plenty to spare. That is indeed a novelty, and one that must somewhat confound those political economists who are ever prating that we don't grow enough of this, that, and the other. Last year we grew far too many Potatos. We not only have wanted none from the foreigner, but we have exported vast quantities, and even now Potatos with us are so cheap they can hardly be given away.

— **THE GENERAL HORTICULTURAL COMPANY (JOHN WILLS) LIMITED.**—On Thursday Mr. ROMER, Q.C., applied to Mr. Justice CHITTY for the appointment of two directors of the General Horticultural Company as provisional liquidators of the Company pending the hearing of a creditors' petition to wind up the Company. The application was assented to by Mr. CROSSLEY, Q.C., on behalf of the Company, which it was said was insolvent. The Company has several branches, and carries on an extensive business. Mr. Justice CHITTY granted the application, and authorised the provisional liquidators to carry on the business in the ordinary way as a going concern, and to expend a sum not exceeding £350 a week.

— **LABELS.**—MESSRS. FISHER, CLARK & CO., of Boston, Lincolnshire, send us specimens of their labels, made of some tough waterproof material which can be written upon with ink, and which it is alleged will bear the longest exposure to the rain. At present we have had no experience as to the durability of these labels, but should they stand the test they will prove a great boon.

— **MANDIOCCA IN BRAZIL.**—The staple article of food in Rio Grande do Sul, Brazil, is stated to be farinha prepared from the tuberous root of the Cassava plant, *Manihot utilisima*. Three years ago there was a severe famine in the northern provinces of the empire caused by drought, which necessarily caused a great demand for farinha. During this time nothing scarcely was grown in any part of the province except farinha. As prices were exceedingly high, they still went on planting, as if the demand were always to remain unlimited. Land was cleared in all directions, to enable them to produce double and treble the quantity they had ever previously grown. Their whole attention seems to have been concentrated solely on farinha, and they are now suffering severely in consequence. Rain came at last in the northern provinces; there were abundant harvests, and in consequence there was no outside demand whatever here for farinha. The quantity produced in this and other provinces was so great that it fell considerably in price, so that a large portion of the crop was allowed to rot on the ground as it would not pay to prepare it. This has been a severe lesson, and the growers are likely to turn it to good account. They are convinced indeed that Coffee is a far superior article to depend upon. The Government of the province of Rio Grande do Sul is doing all in its power to encourage the growth of Coffee, which is of excellent

quality, and they have lately offered £100 to all persons who will plant and produce from 10,000 trees. In two years' time it is probable that large quantities of Coffee will be exported from here both to Europe and the States.

— **ESSEX FIELD CLUB.**—The twenty-fourth ordinary meeting of this Club will be held at the headquarters, 3, St. John's Terrace, Buckhurst Hill, Essex, this (Saturday) evening, at 7 o'clock. The following communications will be read:—1. "The Woolwich Beds at Leyton"—a note by ALFRED P. WIRE. 2. "The History of Botanical Investigation in Essex," by Professor G. S. BOULGER, F.L.S., F.G.S.—Part I.: GERARD, PARKINSON, DALE, and RAY.

— **THYRSACANTHUS RUTILANS.**—It is seldom one sees a better selection of plants for the embellishment of sitting rooms than those exhibited at the late show of the Bristol Horticultural Society, held on the 22d and 23d ult.—notably those from the gardens of LEWIS FRY, Esq., M.P., who, among other first-rate examples, had a plant of the old favourite *Thyrsacanthus rutilans*, grown in a 6-inch pot, with nine drooping racemes of its lovely scarlet flowers, which, hanging gracefully over its healthy green leaves, had quite a fascinating effect. There were many newer and more valuable plants exhibited in the same class, but none that was more admired or more truly beautiful in appearance.

— **HORTICULTURAL CLUB.**—The usual monthly dinner was held on Tuesday last, at the Club rooms, Henrietta Street, Covent Garden, and was well attended.

— **THE WEATHER.**—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending March 20, issued by the Meteorological Office, London:—The weather during the greater part of this period has been characterised by very fine warm days and cold clear nights. By the 20th, however, the sky had become cloudy, and some showers had occurred at nearly all our stations. The temperature has continued above the mean in all districts, the excess ranging from 3° or 4° in the southern and south-western parts of England and Ireland to 7° in "England, N.E." and "Scotland, E." The maxima were very high for the season, a reading of 66° being registered at Scarborough on the 16th, and in London on the 18th; while in many other places the thermometer reached 64° or 65°. The minima, which occurred generally on the 14th or 15th, ranged from 28° over eastern and central England to 35° or 36° in Scotland. The rainfall has been less than the mean in all districts. Bright sunshine has been much more general than for many weeks. The percentages varied from 27 in "Scotland, W.," and 36 in "Ireland, S.," to 66 in "England, E.," and 67 in "England, S." Depressions observed:—During the greater part of this week an area of very uniform and high pressure has existed over England and France, while a few slight depressions passed from west to east to the northward of our islands. Calm and variable airs were consequently experienced over England, and south-westerly breezes in Ireland and Scotland. At the end of the period, however, the distribution of the pressure had changed; the barometer had fallen rather briskly; some small depressions were passing from west to east across England, and the south-westerly wind had spread to all parts of the kingdom.

— **GARDENING APPOINTMENTS.**—MR. SYDNEY WHITE, who has been Foreman at Welford Park, Newbury, for the last two and a half years, is engaged as Gardener to Sir ROBT. MUNDY, Hollybank, Eusworth, Hants.—MR. J. STONEY, late Foreman at Shirburn Castle, Tetworth, Oxon, has been engaged as Gardener to Sir THOMAS EARLE, Bart., Allerton Tower, Woolton, Liverpool.—MR. J. EVANS, late Gardener at Addiscombe Park, Croydon, has been engaged as Gardener to J. L. BROUGHTON, Esq., Broughton Hall, near Ecteshall, Staffordshire.—MR. J. DEVILLE, late of Weyston Lees, Monmouth, has been engaged to Mr. RAONE, Alton Towers) as Gardener to JAS. MEAKIN, Esq., Darlston Hall, near Stone.—MR. HENRY CLARK, Gardener to Mrs. HALL, Syndale Park, Faversham, is engaged (through Messrs. JOHN LAING & Co.) to succeed Mr. CRUMP as Gardener to the Duke of MARLBOROUGH at Blenheim.

NEW FRENCH ROSES.—I know of no point on which a greater change has taken place amongst the rosarians of England, than the manner in which the catalogues of new Roses from over the water are looked for. Formerly—even as lately as seven or eight years ago—there was an exciting desire to see these lists. Happy were they considered to be who obtained a glimpse of the forthcoming novelties; but this was ever and is still a most difficult task. There is never much to be seen about Paris, for although some of the Paris Rose merchants distribute a large number of novelties (?) each year, few are "gained" in the neighbourhood—you must go further south, and at Lyons find yourself in the delightful "terre des Roses"; the names of Lacharme, Liabaud, Guillot père and Guillot fils, Schwartz, Ducher, and Levet, recall to fond memory some of the grandest flowers, but who ever saw much of novelties in flower at Lyons? Roses very soon go out of bloom there, and just before you came there had been a frightful storm—the Roses are all *abîmés*. "You may see, monsieur, the ground is strewn with their poor petals, and there will not be any more in flower until after you are gone: it is very unfortunate." Now and then you may be more successful, and get a glimpse of something fine, but it is rarely so, and I think we may be sure of this, that if we do see anything it is good—it is the indifferent flowers that are always destroyed: this is remarkable, but so it is.

Next to seeing the flowers it was considered a great thing to get some information from some of the growers, and then, when the catalogues did appear, there was an emulation to see them, to let the Rose world know all about them; then our English nurserymen, who were as much in the dark as the amateurs, got some of them propagated quickly, and happy did the amateur consider himself to be who could get a few spindly plants raised in heat, although there was not the smallest likelihood of his getting a flower that season, and perhaps after he had taken the trouble to propagate them he had to throw them all away. Now all these things are a dream of the past; a few of our leading Rose growers take a pleasant trip to Lyons, they see something, or nothing, as the case may be; but it is a "jolly outing," and wears, at any rate, the appearance of business; when they return, they are asked languidly if they have seen anything really good; if they say "Yes," I am sorry to say it is too often received with an incredulous shrug; if they say "No," no disappointment is expressed. The catalogues are published, but there is no rush for them; they are but little noticed in the papers, in proof whereof I may adduce the fact that the present season not one notice has been given of them.

There are, I think several reasons for this. One is the very satisfactory one that we have got such grand Roses that it seems to be almost impossible to excel them. Whether we take the Hybrid Perpetuals or Teas, we may well ask where are we going to obtain anything that shall exceed in beauty Marie Baumann, Charles Lefebvre, Horace Vernet, A. K. Williams, Marie Van Houthe, Maréchal Niel, and a number of other first-rate flowers. Mark the smile of incredulity with which you will be welcomed if you say that you have seen a Rose better than Marie Baumann or Alfred Colomb, and when you detail all that Mons. A. or B. has told you of his new "gain," the smile is no way relaxed; and, in truth, it is exceedingly difficult to excel them. Occasionally "a bright particular star" comes to view amidst the constellations of our rose firmament, but it is a very rare case; hence, as this has gone on for some years, growers have come to consider the long list of sixty or seventy Roses as a mere matter of course; they will let anybody try the experiment of growing them and profit by their experience, while growers for sale do not enter so largely into them as they used to do, and rely more on their knowledge of the raiser than on the descriptions of the flowers, which are too often fallacious. Then there is another reason which is in some way satisfactory, viz.,

that English growers have of late years been raising some good flowers, which although not up to the standard of the best of the French flowers (for we have no English Marie Baumann or Charles Lefebvre), yet a few of them take a place amongst the best first-rate flowers. The chief reason has been, however, the innumerable quantity of worthless flowers which have been sent into commerce; they have come with high-sounding titles and with grand descriptions, but the greater portion of them have turned out to be impostors.

We have this year the usual orthodox number of between sixty and seventy new varieties, divided into the various sections, the bulk being Hybrid Perpetuals. Of these there are thirteen Teas, forty Hybrid Perpetuals, four Hybrid Teas, three Noisettes, two Bourbons, one Perpetual Moss, one Polyantha, and one Rugosa. With regard to the Teas, Hybrid Teas, and Noisettes we may dismiss a good many of them at once, as they are raised by a grower in the South of France, and not one of his has as yet in this country proved worth its manner. They are the delight of the numerous visitors to the Riviera, to whom a Rose in the months of December and January blooming out-of-doors is a real treat, and who would think it too bad to stop and criticise. Out of the twenty Teas, Hybrid Teas, and Noisettes he has thirteen—leaving only seven to all other growers; but if my information be correct—and I have had it from some of our most experienced growers—there is one amongst them which is a Koh-i-noor. I mean *Etoile de Lyon*, raised by Guillot fils, who has already given us some splendid flowers; it is said to be something between *Maréchal Niel* and *Cloth of Gold*, to hold itself up well, as is the habit of the latter variety, its colour a clear bright sulphur-yellow, with the centre somewhat deeper. This is quite enough to make one's mouth water, and happily it has been seen and ordered by those who are not likely to be led astray by a thing's being new. Guillot has another Tea, *Madame Cusin*, of which he gives a glowing description: a well formed strong-halated rosy-purple, with white ground and slightly yellow tint. *Gonod* has one which, if it at all bears out the description, ought to be a beauty—*Beauté de l'Europe*. He describes it as having the form of a *Cabbage Rose*, deep yellow, and the reverse of the petals copper. Imagine, then, a yellow A. K. Williams, but, alas! I cannot form any very strong anticipations of coming joys.

I pass on to the Hybrid Perpetuals: of these Moren and Robert have Albert de Blotais, *Archiducesse Elizabeth* d'Autriche, and *Madame Yorke*. Liabaud sends out *Ampère*, *Capucine Liabaud*, and *Pierre Margery*. Ducher has *Ernest Pernet* and *François Olin*. Leveque et fils send out *Comte Adrien de Gerniny*, *Comte de Flandres*, *Madame Marie Rödener*, *Madame Martha d'Halloy*, and *Tatiana Oueguine*. Schwartz has to give us *Comtesse Henriette Combes*, *Mons. John Twombly*, and *Mons. Jules Vigener* has no less than six—*Eugène Tronson*, *Hippolyte Marchand*, *Intendant Perrie*, *Madame Charles Lavot*, *Madame Gabrielle Mérite*, *Madame Rosalie de Wincop*. Lacharme offers but two—*Helène Paul* and *Violette Douyer*. Guillot has also two—*Jules Mongés* and *Madame Marie Bianchi*. Nabonnard has *La Madeleine*. Schmitt (a new name) announces *Madame Adelaïde Cote*: *Besson* two—*Madame Fortunée Besson* and *Madlle. Marie Chautet*. *Gonod* has *Marie Garner*. *Souper* & *Notting* have *Madame Marie André* and *Madame Anna Grérol*. *Pernet* has *Pierre Duand* and *Berthes*, *Souvenir de Madame Bertha*. Now, taking the pretty safe rule that those who have already given us cause to trust their judgment may be relied on, while those who have heretofore sent us Roses of little value, may be esteemed to be worthless guides, I should then select from these raisers Lacharme, the raiser of Charles Lefebvre, and Guillot de La France, Liabaud of Jean Liabaud, Levet of Etienne Levet, and Schwartz, the raiser or sender-out of A. K. Williams.

In *Helène* (or *Helén*) Paul Lacharme promises us a nearly white Rose of the *Victor Verdier* type. He describes it as a pure white, occasionally shaded with bluish. Several of our growers who have seen it pronounce it to be a great acquisition. He has also in *Violette Douyer*, a seedling of Jules Margotin, another light Rose, what he describes as white shaded with tender flesh colour, perhaps of the *Captain Christy* type (*Guillot*). *Jules Mongés* is described by him as a seedling from *Souvenir de la Reine d'Angleterre*, with large cup-shaped flowers, fine shining

rosy-carmine; the other, Madame Marie Bianchi, must be a curious flower. It is described as lilac, darker in the centre, back of petals white, and, what is very rare amongst French raisers, it is stated to be the issue of artificial hybridisation between Victor Verlior and Virginale. Liabaud has Ampère, a seedling from Lion des Combats, carrying one very far back, to a long-forgotten Rose, dark purplish-crimson. Capucine Liabaud is described as being of a brilliant carmine-red, but it is said to be only nearly full. I fear that it is one of those open flowers of which he has already given some examples. Pierre Margery is described as a full flower, very bright rose, brighter at the centre. Schwartz' Comtesse Henriette Combs is described as of the Centifolia form, satiny rose, back of petals white. John Twombly is said to be of a lively currant-red; and Jules Grévy—the result again of artificial hybridisation—viz., of Triomphe de l'Exposition and Madame Falcot—is said to be salmony-white, the exterior of petals lively salmon-rose. Levat has Madame Bruel, a seedling from Comtesse d'Oxford, colour carmine-rose; Madame Crozy, a seedling of Souvenir de la Reine d'Angleterre, colour of the China Rose; and Ulrich Bruner, a seedling from Paul Neyron, with large petals, and of a cerise-red colour, another Titchborne.

All who know the pretty little Paquetette, or Daisy Roses, so profuse in blooming and pretty in habit, will be glad to hear that Guillot has in his Mignonette a very pretty rose-coloured one.

In addition to these M. Eugène Verdier, a most prolific vendor of new Roses, announces that owing to the severe winter of 1879-1880, he has been unable to put into commerce this season any of the magnificent gems "of which he has more than 400 in course of study!" With a liberality rare indeed he offers to sell the entire stock, both of those that have flowered and those which have yet to bloom. Well, we shall have in one way or other plenty of novelties, by-and-by; in the meantime we shall look forward to the blooming of the Roses I have named, for several think that it will be a notable year for new Roses. *Notes verveux, Will Ross.*

TEA ROSE LADY MARY FITZWILLIAM.—Blossoms of this fine hybrid Tea Rose (Hevonensis × Victor Verdier) have reached us from Mr. H. Bennett, of Shepperton. They are very large, very full, the petals broad and recurved, the colour flesh-pink; and very fragrant. The leaves are glabrous, and the wood moderately prickly.

HOME CORRESPONDENCE.

The Weather.—Winter came yesterday (March 21), when a few showers of snow fell. During the night biting winds, drifting snow, and hailstorms, and a few degrees of frost. To-day (22d) hail and storm showers alternating all day, with a few gleams of sunshine; wind sharp and biting, likely to be a sharp frost to-night. Wind north-west. Peaches, Nectarines, Apricots, in full and glorious blossom; Plums just about to open. Hurried on our screen of boughs yesterday: fearful of result. Apples and Pears backward, and safe against several degrees of frost. *D. T. Fish, March 22.*

The Bone-Tree.—In September last you were so kind as to devote a portion of your columns to an article on the Bone-tree; will you allow me to call your attention to the enclosed letter from Captain Maclear, commanding H.M. surveying ship *Alert*, which appeared in the *Standard* of the 10th inst. —

"Sir,—In August last there appeared in the *Standard* a letter from Lieutenant de Hoghton about the pearl-shell fisheries in Torres Straits. In this he mentioned a curious tree that picked up bones. The account was so curious that I wrote to Mr. Chester, the resident magistrate at Thursday Island, for an explanation, and I think his answer will interest you. — "I have made inquiries about the tree, and I find that it grows at Marbae, not far from Pearson's Station. It is a kind of Banyan, or Fig tree, and sends down long vines, or tendrils roots, from its upper branches; these run along the ground, and from time to time small detached in their path, such as bones and other unconsidered trifles. The vines afterwards contract, and draw up whatever is attached to them. This is Pearson's explanation of the phenomenon.—I am, sir, your obedient servant, *J. P. Maclear, H.M.S. 'Alert,' Colombo, Feb. 18.*"

From this it would really appear that, besides myself, there are three other people "living in the nineteenth century who believe a tree capable of dealing in bones

in the manner described;" and I live in hopes that, when investigated, other people, and perhaps even the Editor of the *Gardeners' Chronicle*, come round to the same belief, and acknowledge that "the confiding bone merchant," you so aptly portray as slumbering beneath its shade, might find his bones actually, and himself metaphorically, "up a tree," when he finished his nap, so I recommend the said bone merchant to give Jersey Island (or Marbae) in general, and Philip Harbour (that island in particular, a wide berth, for that harbour stands the "Bone tree," *Thomas de la Motte, Commander Royal Navy, St. Leonard's, March 20.*

Earliness of the Season.—Herewith I send, as specimens of the earliness of the spring, even in cold Yorkshire, — (1) a small branch cut from an unpruned hybrid perpetual Rose bush growing in an open border, on which, as you will see, the buds are quite visible; (2) an Apricot that I picked myself from a young tree growing at the south end of a farmhouse near here: of course a fireplace regularly in use at the north side of the wall has much to do with the size of the Apricot, all the fruit similar to the one sent being in a space of 2 feet square. The trees and branches are just setting, still Apricots are large as small Walnuts, even with the aid of fire-heat mentioned above, are not common in the middle of March from unprotected trees even in ordinary early seasons. *H. P. Clayton, Grimston Park Gardens, Tadcaster, March 15.* [From Thorpe, near Halifax, we have received strong evidence of the mild season that has been experienced in that part of (West) Yorkshire. Ed.]

Bees in Peach-houses.—It is an old-fashioned plan, and one not generally recommended now, to put a hive of bees in a Peach-house when the trees are in bloom. I think, however, much may be gained by doing so. A week or two ago the Peach trees in an unheated house here were in full bloom. Many dull days happened at the time, and, as we had not the slightest control over the atmosphere in either low temperature or excessive moisture, I felt rather afraid of the result, my only hope being in the bees, which had been used in another house, and which I had brushed-fertilising of the blooms was never attempted, but the bees were very industrious, and the fruit of their labour is now visible, as the specimen of "setting" which I send you is an ordinary sample of what may be seen all over the house. *J. Muir, Mangon, S. Wales.* [A very good "set." Ed.]

Seedling Abutions.—I am glad to see that these useful plants are being brought out so well. All lovers of flowers will find them well deserving of attention. They are easily propagated, and easily grown, and altogether well deserving of extensive and general culture. Some of the old named sorts were good, but many of the new seedlings are better, and amongst the latter there is one here which I consider of more than ordinary merit. There is only one plant of it in bloom at the present time. It is eight months old, and is growing against the end of an intermediate-house. It is not a very large plant, as it has always flowered so freely that wood and leaves were made slowly. If every branch was cut off they might easily be held in one hand, and all the blooms which are open on it this day (March 21) I send to you. They are eight dozen in number. Throughout the winter hundreds of blooms have been cut from it, and it is no exaggeration to say that now there are thousands of buds on it to open. For compact growth, prolificness, and size and colour of its deep rich golden flowers, I have seen none to equal it. *J. Muir, Mangon Park, S. Wales.* [Evidently a first-rate variety. Ed.]

The Conservatory at Longford Castle.—Just now the conservatory at this extensive gardening establishment is exceedingly gay, and doubtless will be so with spring flowering plants for some few weeks to come. The roof, which is wired, and over which those two admirable climbers, *Tasmania Van Volxemi* and *exoniensis*, grow, is in itself a sight worth seeing at any time of the year. With regard to these two *Tasconias*, it may be as well to remark that in their training and tying, anything and everything pertaining to stiffness or formality is strictly avoided. The object appears to be to imitate Nature as far as practicable, and thereby to obtain the best possible effect, and, as regards flowering, the most satisfactory results. Here there are festoons and streamers waving and dangling to and fro in the air, as the ventilators are opened, and bedecked with their curiously-shaped and beautiful crimson-coloured flowers, each depending from the shoot on which it is borne by its long and slender thread-like footstalk. Altogether the roof has a most chaste and lovely appearance when the plants are in full flower. As evidence of the suitability of *Tasconias* for a cool house, it may be mentioned that the plants under notice have been flowering continuously for the past eighteen months or two years. Amongst the other occupants of the

structure are well-grown and well-flowered examples of *Spiraea*, *Arum*, *Eupatorium*, and *Lily* of the Valley, &c., in abundance. Nothing could be more simple or more successful than Mr. Ward's way of treating *Lily* of the Valley. The roots are strong impored clumps, and are potted mostly into 5 and 6 inch pots; according to the time they are wanted in flower so they are brought into the Mushroom-house, and covered with about 6 inches of decayed leaves; here they remain till the crowns have started well into growth, then they are transferred to one of the forcing-houses, where there is plenty of heat and moisture. By adopting this plan, both leaves and flowers come away simultaneously and are both fully developed at the same time; *Eupatorium riparium* and *Arums* are well done, and two more useful plants for cutting from at this time of the year cannot well be imagined. They are like all other good things, *i.e.*, worth doing well, and will pay for liberal treatment. If planted out early in the summer and grown in a rich open border containing a few barrowsload of turfy loam, and potted up towards the end of September, the results will be highly satisfactory. In addition to the above there is also a very choice and varied collection of *Solanums*, *Cyclamens*, *Primulas*, *Calceolarias*, and *Cinerarias*, together with many other miscellaneous subjects too numerous for special comment. Seeing that there has recently appeared in your columns a paragraph or two both *pro* and *con* respecting seedling *Cinerarias*, I may here state that at Longford Park are a few seedlings, and that they are a superb collection, too. Although further selection may be necessary before attaining the ideal standard of excellence which a technical florist would require, the strain itself is of such a character that any one who has to grow for market or furnishing would not, with seed of it in their possession, think for a moment of growing or perpetuating named varieties. Some of the selfs are exceedingly good, and leave little for the most fastidious of critics to desire, being in form, colour, size, and substance all that one could wish. Written from memory, I think I may safely state that many of the individual flowers would easily cover half-a-crown, and some of them possibly a crown piece. Where this is the case the reader may be sure the plants are well grown, some of them measuring from 18 inches to 2 feet high and something like 3 feet through. *J. H.*

Trickery in Plants: a Caution.—Last year about this time or a little later a man was seen in Maidstone with a tray of young plants offered them for sale at twopence each—a single shoot from 2 to 3 inches high, each plant separate, pressed tightly into a lump of fresh wet loam, about the size of an egg; he called them "the new Brazilian Musk," the plants being very strongly scented with that perfume. He stated that Mr. Ladds, of Bexley Heath, supplied him with plants as he wanted them. A friend of mine purchased a plant which I happened to see afterward, and told them it was "the Musk" at all, although the smell was the same; but the plant was potted to grow on, and in a few days it was scentless but healthy. It remained in the pot till in bloom, when it proved to be the Dead Nettle, *Lamium album*, and must have been scented with Musk in their young state on purpose for sale. Of course, then it was too late to find the man, or who he would have been handed over to the police. *H. Thiers, Wotton.*

DORYANTHES PALMERI.

A SPECIMEN of this noble plant is now coming into flower in the southern octagon of the Temperate-house at Kew. We had occasion to mention and to figure the plant a few years ago (1874, vol. i, p. 181), our illustration being taken from drawings made in Queenland. We reproduce a figure (fig. 64) showing a small portion of the inflorescence. This is, we believe, the first occasion of its flowering in this country, and the stately grandeur of the plant is such that we recommend all those who have the opportunity and the space to avail themselves of it. Imagine a bold dense tuft consisting of very numerous broad lance-shaped leaves, each about 6 feet long by 6 inches in breadth, gracefully arching over, a mile from the centre of the tuft of leaves arises to a height of 10–12 feet a slender column, clothed with appressed leafy bracts, and bearing at the summit a compact, many-flowered panicle of large 6-parted funnel-shaped flowers, at present somewhat dull-red in colour. Whether as the growth continues this will be exchanged for the brighter hues which characterise the plant in its native country remains to be seen.

THE Twickenham Horticultural and Cottage Garden Society's thirteenth summer show will be held in the grounds of the Orleans Club on July 7.

Florists' Flowers.

CHINESE PRIMULAS AT READING.—The *Primula sinensis* has of late shown a tendency to variation that could never have been dreamed of by the gardeners of the past generation. Time was when, if a nurseryman received an order for Primulas, he would go to the seed-pans and select the red-stalked plants as purple-flowering, and the white-stalked plants as white-flowering varieties. It is no longer safe to do this. One of many results of intercrossing has been that we now get flowers of snowy whiteness on plants

The Fern-leaved section appears to be prolific of floral surprises. A new type, provisionally named *Rosy Pink*, is of an exceedingly attractive hue of colour—soft and expressive, and in addition has a vigorous and yet compact habit of growth. There is also a double form, of this rich rose colour, also on Fern-leaved foliage, but if anything the colour is more intense, and it makes a charming pot plant. There are also the Fern-leaved type, with rich purple flowers—one in particular, with a rare vividness of tint. This came in a somewhat unlooked-for manner among some special crosses, and the flowers, being large, finely-formed, and rich in colour, and the habit of growth dwarf, compact, and yet vigorous, will make a good parent. There is a new type of white Fern-leaved, in which the flowers are of the purest white, and also

should be fertilised with their own pollen, to keep it pure in colour. Side by side with this could be seen growing the best variety of white Primulas, of others' raising, that Messrs. Sutton & Sons had been able to obtain. This practice enables them to form comparisons, and this is decidedly advantageous in selecting seedlings. One seedling, marked $\times 29$, represents a selected type obtained from a cross between a fine white and *Toukings' Princess Louise*, that produced flowers of astonishing size—large, stout, and exceedingly well formed—a stiff habit and dwarf foliage, and with the trusses well above the leaves. This will make a very fine variety for exhibition purposes.

Ruby King, the new deep blood-red coloured variety, was in fine form this year, and being late in

FIG. 64.—*DORYANTHES PALMERI*: BRANCH OF THE INFLORESCENCE. (SEE P. 408.)

with coloured leaf-stalks, and coloured flowers on plants with pale or white leaf-stalks. A larch of seedlings raised from seed taken from flowers carefully and intelligently fertilised will be found pregnant with floral surprises of a peculiarly interesting character. There is no end to the infinite variety Nature has stored up in her marvellous storehouse, and the Chinese Primrose appears capable of indefinite illustration of varying tint.

The London Road Florists' Seed Grounds of Messrs. Sutton & Sons at Reading may be likened to a floral laboratory where experiments in fertilisation are tried, and with decided and substantial successes. In early spring the Primulas of the *sinensis* type afford a rare floral treat. They are both well grown and bloomed, and consequently one sees them in their best character, and can properly appraise their merits.

of large size and substance; it also flowers with great freedom, as many as three and four good trusses being seen on quite small plants, and so forming dense pyramids of flower. This is a charming variety for decorative purposes. The selected white and red Fern-leaved types are also very fine.

Of the plain-leaved section there are many fine types. The selected red, superb red, blush and pure white types, are all very fine; but these have to give way to newer selections of a very valuable character. One, named *Snowdrift*, is really a pure white Primula, that is to say, from the time the flowers expand till they decay not a trace of blush comes on to them. This is the common fault of some of our finest white Primulas, but we are surely reaching on to a strain when the purity of the whiteness will be undimmed by time—the trusses of this variety stand up so well above the foliage. The flowers of this fine type

flowering helped to keep up a good succession. As a selection is made every year for seed purposes, a gradual but sure improvement goes on. *Reading Pink* is of the same colour as *Suttons' Rosy Queen*, on Fern-leaved foliage, and in both cases, while the colour is especially pleasing, the flower-stalks are borne well above the foliage. A new selection, numbered $\times 60$, is of a very bright red colour—quite a new shade of red, reminding one of *Ribes sanguineum*—flowers large, very stout, and the best shape and substance, the habit excellent in every respect. A new selection, with pretty soft lilac-pink flowers—quite a new shade, has been named *Princess Beatrice*. This deepens to a bright pink as it ages, but retains a distinct and novel tint, the segments being margined with white and flaked with the same: thus promising to furnish a new type of striped Primulas. The flowers open nearly pure white, and deepen in

insure the equality or uniformity of conditions, or to make correct allowance for their difference, and at least one very ingenious instrument by receiving the air into different pipes, opening different valves according to its varying strength, and then giving out two similar, but distinct musical notes, the one of which answers to a definite direction, the other to a definite velocity. Such things can, at present, only be considered as pretty and ingenious toys; they can undoubtedly mark a difference between one wind and another, but are quite unequal to giving any exact measure of relative, and still more of absolute force. Even the more generally recognised types of anemometers, the very commonly used pressure plates of Mr. Ostler, or the revolving cups of the late Dr. Robinson, are by no means entirely satisfactory. The action of stream lines in front, or of the partial vacuum behind the exposed surface, leads to curious vagaries difficult to understand, and as yet impossible to correct. But till they are understood and corrected, anemometers, as a scientific standard, are very uncertain.

The President, in conclusion said, that what we want is not so much new and improved apparatus for registering or recording; for though those we have are not perfect, they are far superior to the anemometers they are applied to. The question is, how can we get a more exact result in the instrument itself, or in the theory which translates its action. It is to this that we would wish more especially to call the attention of all meteorologists.

In connection with the meeting there was an exhibition of instruments, consisting of anemometers of various meteorological types, &c. The anemometers exhibited were forty-five in number, and included, among others, those of Beckley, Biram, Cator, Hagemann, Howlett, Lind, Lowae, Osler, Oxley, Robinson, Ronalds, Somerville, Whewell, and Wild. There were also photographs and drawings of old forms of anemometers, damaged caused by whirlwinds, &c.

Scottish Horticultural Association. — The annual meeting of this Association, held on Tuesday, the 7th inst., at St. Andrew Square, Edinburgh, Mr. Downie, President, in the chair. There was a good attendance. The Secretary, Mr. A. Milne, read the report, which congratulated the Association on the work of the past year. There were now upwards of 400 members on the Association's books, and 25 new members had been added during the year, being an increase of four, compared with the number enrolled last year. Twenty papers had been read, and ten Certificates had been granted by the adjudicating committees for new plants, fruits, and vegetables, which the Association had also been awarded to three members for the superior culture of flowers. Thirty-one members had exhibited collections of plants, flowers, fruits, and vegetables, during the year. The report of the Treasurer, Mr. D. P. Laird, showed that the income for the year, including balance from last account, amounted to £64 5s. 6d., and the expenditure to £41 11s. 0d. The reports were adopted. A discussion took place on the desirability of having a journal or periodical started under the auspices of the Association. It was ultimately resolved, on the motion of Mr. Hugh Fraser, President, that the Council of the Association to appoint a sub-committee to inquire into the whole matter, and to report to a future meeting. Mr. Dunn, Balkeith, reported that five essays had competed for the prizes offered by the Association for the best essay on the "History of Hardy Fruit Culture in Britain," and the judges had awarded the prizes to the essays bearing the following notices: — 1, *L. Supra*, Mr. George Oliver, Royal Botanic Gardens, Edinburgh; 2, *Terna verna molitorum arena*, Mr. Mark King, Edinburgh; 3, *Beaumontia*, Mr. Peter McFavish, Ardrey Castle Gardens, Sirling. Four cases of insects injurious to plant life were exhibited by Mr. George Oliver, Edinburgh Royal Botanic Gardens, and he was awarded the 1st prize for his collection, which was commended by the judges for its arrangement and appearance. Everett Professor Balfour was elected Hon. President; Mr. Hugh Fraser, Leith Walk Nurseries, was elected President; and Messrs. J. Downie, A. McLeod, and F. Muoro, Vice-Presidents. The Secretary and Treasurer were re-elected. To the retiring President a certificate of thanks was accorded.

Mr. Robertson Muoro, Abercorn Nursery, exhibited a collection of hardy spring flowers, which were very much admired. It included Primulas, Hepaticas, Saxifragas, and Scillas. Mr. Chapman, Easter Duddingston Lodge, exhibited specimens of the following plants: — *Phlox phurum*, Scillas of sorts, and Saxifraga Bursertiana; while Mr. George McKinnon, Melville Castle Gardens, displayed some flowers of *Cilanthus pinnatifidus* in remarkably fine bloom for the season.

Law Notes.

COURT OF APPEAL: *Lincoln's Inn, Monday, Jan. 20.* — [Before the Master of the Rolls and Lords Justices Cotton and Lindley.] *The Commissioners for the Exhibition of 1851 v. The Royal Horticultural Society.* — This was an appeal by the plaintiffs from an order made in June last by Mr. Justice Fry, dismissing the action with costs. The trial lasted five days and was fully reported by us at the time.

The plaintiffs were the owners of considerable land at Kensington, and in 1860, being anxious to promote the science of horticulture, they granted to the defendants a lease of certain land (now known as the Royal Horticultural Gardens) on very favourable terms, but the provision upon which the case was de-

vised by Mr. Justice Fry was one to the effect that the amount of rent payable should be to a certain extent contingent upon the receipts of the gardens, and for the purpose of ascertaining this amount from time to time a Joint Expenses Committee was appointed. The plaintiffs' action was to compel a forfeiture of the lease, on the ground that no rent had been paid for many years, and that they were therefore entitled to re-enter and take possession of their land. It appeared, however, that owing to various causes the Expenses Committee had not met for a very long time, and the defendants therefore contended that the amount of rent due, if there were any, had never been ascertained or demanded. Mr. Justice Fry held this objection to be fatal to the plaintiffs' case.

The debenture-holders were also parties to the action, and they submitted that the plaintiffs and the defendant Society were practically partners, and that in any case their debentures should be satisfied before re-possession was obtained.

The plaintiffs now appealed.

The Solicitor-General, Mr. Crossley, Q.C., and Mr. Beaumont appeared for the appellants; Mr. Fischer, Q.C., and Mr. Haughton for the respondents; Mr. Cookson, Q.C., and Mr. De Castro for the debenture-holders.

The SOLICITOR-GENERAL went through the various agreements set out in our previous report, and contended that the mere non-constitution of the Expenses Committee did not deprive the plaintiffs of their right of re-entry.

THE MASTER OF THE ROLLS: It would be very unjust if it were so. The respondents could by that means evade payment of rent altogether, by simply preventing the committee from meeting.

Mr. FISCHER said that as a matter of fact the plaintiffs themselves were the only persons to blame for the non-constitution of the committee.

The SOLICITOR-GENERAL admitted that that was so, but there could be no doubt as to the Society's inability to pay the rent, and, indeed, the Horticultural Gardens had failed. With regard to the debenture-holders, the learned counsel contended that they could not have higher rights than the Society itself, and he repudiated the idea of a partnership existing between the Commissioners and the Society.

Mr. FISCHER, Q.C., submitted that the non-constitution of the committee had prevented the ascertainment of the amount of rent payable. The Horticultural Society had never placed any obstacle in the way of the committee, and were most desirous that it should meet. The Society had the interests of the debenture-holders to consider, and therefore they were obliged to stand upon the letter of the agreement. The bargain between the parties might have been unusual, and even unwise, but at the same time it was binding. Between the years 1874 and 1875 there had been differences between the members of the committee, but in the latter year those disputes were settled, and since then the Society had repeatedly applied to the Commissioners, who had, however, refused to meet, therefore there had been no legal failure as to payment, and the plaintiffs ought to be non-suited.

On Tuesday, Mr. COOKSON, Q.C., addressed the Court at length in support of the case of the debenture-holders. He contended that even if the plaintiffs succeeded in the action, provision should first be made for the debenture-holders, who had been induced to subscribe their money upon the faith of the lease being free from all question. Indeed, the re-entry clause had been inserted after the money was subscribed, and therefore ought not to bind the debenture-holders. The arrangement between the Commissioners and the Society amounted to a partner ship. The whole affair was purely a commercial speculation, and no relation of landlord and tenant existed between the parties.

The argument in support of the debenture-holders' case lasted the whole day, and at its conclusion the Court intimated that they did not desire to hear the plaintiffs in reply, and were willing to adjudge in the morning.

On Wednesday, March 22, the MASTER OF THE ROLLS, in giving judgment, said the Court had come to the conclusion that Mr. Justice Fry had put a wrong construction upon the agreement. The Society had entered into an agreement with the Commissioners to take a lease from them for thirty-one years, which it was eventually arranged should be renewable for another term of twenty-one years, of certain garden ground at Kensington. The Commissioners, having regard to the character of the Society and the object for which the lease had been required, were willing to grant very liberal terms, and they agreed that no rent should be paid in the first instance, but that they (the Commissioners) should advance £50,000 to complete the necessary buildings, &c., on the ground, and that the Society should raise a similar sum, and that the Commissioners should get for rent the yearly sum of £2145, which was 4 per cent. on the sum advanced to them. That was to be subsidiary to the payment of the expenses of keeping up the garden and the payment of interest to the persons who advanced the £50,000 to the Society. The net rent of £2145 was to be paid, and the surplus, if any, was to be divided equally between the Commissioners and the Society. Naturally, the Commissioners wished to retain some control over the expenses of the Society, and it was suggested and agreed

that there should be a regulating committee of six persons, three nominated by the Society and three by the Commissioners, of whom one of the Commissioners' nominees should be chairman. The Court below held that the Commissioners should have a preponderating vote in the committee; then for the protection of the Society there was a clause that the committee should allow reasonable and necessary expenses. There was, however, no power to enforce a meeting of the committee, although it had been suggested in the Court below that a *mandamus* might be applied for, but even if the committee could be compelled to meet how could they be compelled to give a decision? But surely the Society could not have been placed in a worse position in consequence of the committee not having met, for the authority of the committee was limited; they were bound to allow fair and reasonable expenses, and if the Society thought that the committee had failed to allow any proper items they had the right to go to arbitration, either to the court or to the matter. Now, it was clear from the agreements that the £2145 for rent was reserved only by way of interest on the £50,000 advanced by the Commissioners, and if they did not get that, the arrangement was to come to an end, and they were to be entitled to take possession of the land again, and put an end to all the agreements. Therefore the question for the Court was, had there been such a failure? The Society did not deny that there had been, but they said "You cannot find out whether or not there has been a failure until the committee have met, and the committee have not met by reason of your own refusal." That argument, however, would not hold good. There would be something in it had the expenses of the Society been unreasonable, but there was no suggestion of that sort from any of the parties. It had been proved that no rent had been paid since the year 1874, and that was *prima facie* evidence that there were no funds to pay it with; however, it was seen from the accounts of the Society, which were in evidence, that for several years past the receipts in excess of expenditure had not been sufficient to even pay the interest on the debentures. Therefore, as regards the Society, there had been no defence whatever to the action. As regarded the debenture-holders, who had very properly been made parties to the action, they took a different position altogether. They said they were induced to lend their money upon representations made by the Society, by which the Commissioners were bound, and that those representations prevented the Commissioners from taking advantage of the forfeiture, and then they had contended that on a fair construction of the debentures, and having regard to the events which had happened, the Commissioners were not entitled to re-enter without providing for the debentures. In the opinion of the Court those contentions could not be sustained. There had been no representation of a fact which was untrue, and the debenture-holders must be taken to have known exactly the terms of the lease, upon the security of which they advanced their money. It had also been contended that the arrangements amounted to a partnership between the Commissioners and the Society. There certainly were some elements of a partnership, but not all. The Commissioners were not to receive profit, but only part of the surplus after paying expenses of keeping up the gardens and the interest on the debentures. No partnership had been intended, nor had any existed. The debenture-holders had advanced their money to the Society and not to the Commissioners, and any rights of the Commissioners had not to be defeated by the claims of third parties.

On these grounds the Court had decided to allow the appeal, and the Commissioners would therefore be allowed to re-enter and take possession of the gardens.

The plaintiffs' counsel stated that the Commissioners had no desire to press the Society unduly, and they would consent not to take possession for four months.

The action, therefore, was ordered to be dismissed, the Society and debenture-holders paying all the costs.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

GREAT INTERNATIONAL HORTICULTURAL EXHIBITION, To be held in Edinburgh on Sept. 13 and 14, 1882, when £1100 will be offered in Prizes.

SUBSCRIPTION LIST.

Table listing subscribers and their contributions to the exhibition. Columns include names, addresses, and contribution amounts in pounds and shillings.

Subscriptions received by—JOHN STEWART, Esq., W.S., 4, Albany Place; or, Mr. WILLIAM YOUNG, 53, South Bridge, Edinburgh, from whom the List may be had.

LIVE GUANO, SUITABLE FOR ALL CROPS. Price, £3 10s. per Ton, in Bags, at Aylesbury.

A single 1 cwt. Sample Bag sent, Carriage Paid, to any Railway Station upon receipt of Post-office Order for 5s.

This valuable Manure, prepared from Sewage by the "A B C" process, has been extensively used, for several years, by Farmers, Gardeners, and others, whose reports testify to its fertilizing properties.

EXTRACTS FROM LAST SEASON'S REPORTS:—

WILLIAM CRUMP, Gr. to Duke of Marlborough, Blenheim Palace Gardens, December 12, 1881.

"Used for Vines, Peach trees, and other fruit trees, also Potatos, Carrots, Parsnips, Onions, &c. Results: satisfactory. Fruit trees assumed rich dark green foliage, increased vigour, whilst the Fruit swelled up to a very fine size. Potatos came out splendid condition; other roots too were benefited by its application. No other manure used with Native Guano. Undoubtedly a valuable fertilising agent, and I shall lose no opportunity of recommending it to gardeners and others."

A. BLAKE, Head Gr. to H. Casenove, Esq., The Lilies, Wotton, January 3, 1882.

"Used for Peas, Potatoes, Onions, Cabbages, Cauliflowers, Celery, Vines, Cucumbers, &c.; & Chrysanthemums, Primulas, Geraniums, Fuchsias, &c. Results: Onions, Cabbage, Cauliflowers, and Peas good; Cucumbers, first-rate; Potatos, a good crop, and I consider it a good manure for pot plants. I think the Native Guano only requires to be more known to the public to be largely used."

Sixteen Prizes awarded at Birmingham Show, 1881.

The Annual Show of Farm and Garden Produce, grown with Native Guano, will be held at Aylesbury in October next. Schedules and Prizes and all particulars, together with testimonials, &c., may be obtained upon application to

The Native Guano Company (Limited), Aylesbury, Bucks.

"THE COVENTRY."
(REGISTERED).

NETTLEFOLD & SONS desire to call especial attention to their "COVENTRY" LAWN MOWER, which they can confidently recommend as the best and cheapest in the Market.

It has all the improvements which have of late been introduced into this class of Machine, either in England or America; and for the manner in which it does its work, its lightness, and the ease with which it can be used, cannot be surpassed.

Its cheapness brings it within the reach of every one, and in this respect it defies competition with any American machine before the public. It is made, as its name implies, at Coventry, by skilled English workmen, and of best English Steel and Iron. These Machines can also be supplied with ROLLERS AT SAME PRICE, and GRASS BOXES at a small extra cost.

MANUFACTURED BY

NETTLEFOLD & SONS,
54, HIGH HOLBORN, LONDON, W.C.

KEITH'S PATENT "CHALLENGE" BOILERS,
FOR HOT-WATER HEATING.

Can be Heightened or Lowered to suit any requirements. They stand complete in themselves, and require no building work round them, being wholly "water jacketed," and thus entirely free from risk by fire.

These PATENT "CHALLENGE" BOILERS have about ten times the heating surface of the ordinary Saddle Boilers, and are certainly THE BEST, MOST POWERFUL, and MOST ECONOMICAL Hot-water Boilers in use.

See Prospectuses, References, &c.

One of these Boilers has been over a year in use, heating 7500 feet of 4-inch pipe (or nearly 1½ mile of pipe), at the Water Gardens of Isaac Holden, Esq., Oakworth, Keighley. This Boiler has only a 30-inch square fire-grate surface, and has 306 square feet of effective heating surface directly over the fire.

JAMES KEITH,
Gas and Water Engineer,
EDINBURGH and ARBROATH.
Post Address—EDINBURGH.

NOW READY, A REVISED EDITION OF THE

COTTAGER'S CALENDAR
OF

How to Destroy Weeds, Moss, &c., on Gravel Walks.—Use

SMITH'S celebrated **WEED KILLER**, the most successful thing of the day. It is a liquid preparation which when mixed with cold water, and applied with an ordinary watering-can, proves thoroughly destructive to all vegetable growth. For particulars and a List of first-class Testimonials, address to the manufacturer.

MARK SMITH, Chemist, Louth, Lincolnshire.

The **WEED KILLER** is sent carriage paid to any Station in England or Scotland.

DENYNS Unrivalled **ROLL PAPER** and **CLOTH**, as supplied to over 300 Nurseries, 14 1/2, St. 7, 28 1/2, 152, 7, Court, 702, J. DENYN, Manufacturer, 73, Rendisham Road, Clapton, London, E.

TOBACCO PAPER and CLOTH, for **FUMIGATING**.

In splendid condition, specially picked and guaranteed solely the paper and cloth packed round the raw Tobacco and saturated with the pure juice. *Numbers of the cloths, stained, manufactured paper that will kill both plants and fly. Numbers of instances can be quoted where this has occurred. Our paper will last twice as long as the spurious article, will in no way injure the plant, but effectually destroy the fly. Paper and Cloth, 12 per pound. References to hundreds of Nurserymen and Gardeners. Postage Orders payable at Batham Hill.*

TURNERS, Sole London Depot, 45, Batham Grove, S.W.

GISHURST COMPOUND.—Used by many of the leading Gardeners, since 1860, against Red-spider, Mildew, Thrips, Greenfly, and other Blight, in solutions of from 1 to 2 oz. to the gallon of soft water, and of from 4 to 16 oz. as a winter dressing for Vines and other Trees. Has outwitted many preparations intended to supersede it. In Boxes, 12, 36, and 108, 6d.

AMERICAN BLIGHT ON APPLE TREES CURED by rubbing a wet hard Painters' brush on Gishurst Compound, and working the latter into the infected parts.

GISHURSTINE keeps feet dry, softens hard boots, preserves leather, takes a polish. In boxes, 6d. and 12, each.

Wholesale by **PRICE'S PATENT CANDLE COMPANY** (Limited). Retail by Seedsmen and Oilmen.

REGIATE SILVER SAND.—Coarse and fine, on rail at 2d. per ton—not less than 4-ton trucks. Terms cash.—Apply to **H. SIMS**, The Frany, Regent

Oil Paint No Longer Necessary.
HILL AND SMITH'S BLACK VARNISH,
for Preserving Ironwork, Wood, or Stone.
(Registered Trade Mark.)

This VARNISH is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received.
Sold in Casks of about 29 gallons each, at 15. 6d. per gallon at the Manufactory, or 15. 3d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL.
"Pierrefield Park, June 24, 1876.—SIR.—I have this day forwarded from Chepstow to your address, a black varnish cask, to be filled and returned with as good Varnish as the last we had, which I candidly admit was the best we ever had. Address Varnish to Pierrefield Park, Chepstow.—I am, Sirs, yours respectfully, Wm. Cox."

CAUTION.—HILL & SMITH would particularly warn their Customers against the various cheap Varnishes now so much advertised.

H. & S.'s Varnish has been an article of common use on most of the large estates in the Kingdom for upwards of thirty years; and their constantly increasing trade in it, and the numerous Testimonials they receive, stamp it as a truly genuine article. Every cask is legibly marked with their name and Registered Trade Mark as above, without which none is genuine.
Large Illustrated CATALOGUE of Fencing, Hurdles, Field and Entrance Gates, &c., sent free on application to
HILL AND SMITH, Brierley Hill Ironworks, Staffordshire;

MAW AND CO., Benthall Works, Broseley, Shropshire.

THE "AUTOMATON."

Sizes, 8 to 24 inches.
THE BEST GENERAL PURPOSE MACHINE.

The "AUTOMATON" Lawn Mowers are thoroughly strong, well-made, and durable machines, and the best suited for general work and Gardeners' use. They cut the grass perfectly, leave no ribs, but produce a smooth velvety surface on the Lawn, and are light in draught.

The "AUTOMATONS" have front rollers for general work, and side rollers for cutting long grass, or when it is unnecessary to roll the grass in front of the cutters. They have the best machine made gearing, the best self-sharpening knives of steel and iron rolled together, and automatic silent drivers.

R. H. & J. also manufacture
"REVERSIBLE" Lawn Mowers for Small Gardens and Borders, and
"HORSE-POWER" Lawn Mowers for Large Lawns, &c.

THOUSANDS IN USE.
SENT CARRIAGE PAID.
MONTH'S TRIAL ALLOWED.
NO CHARGE FOR PACKING.

COMPLETE PRICE LISTS FREE BY POST.

STOCK KEPT IN LONDON at Arch 92, Spitalfields Station, Bethnal Green, E., and Machines may be ordered from any respectable Ironmonger.

Ransomes, Head & Jefferies,
ORWELL WORKS, IPSWICH.

THE "WORLD."

The "WORLD" (date "GLOBE") Lawn Mowers are intended for cutting long grass; and, whilst similar to the Lawn Mowers imported from America, have the special advantages of the more accurate fitting and general durability of English manufacture and perfect adjustment.

The "WORLDS" will cut wet, dry, long, or short grass without clogging, and cut off almost all the "heats." They leave the surface smoother than similar machines, and are well adapted for getting over a large amount of work with little labour.

Sizes, 8 to 24 inches.
FOR CUTTING LONG GRASS.

THUYA WAREANA, an immense quantity of fine specimens up to 10 feet. AUREA, 2, 3, and 4 feet high. SEMPER AUREA, 2 to 3 feet high, 4 and 5 feet in circumference. RHODODENDRONS of all Colours, and for the most part well budded; many thousands of fine specimens, 3, 4, 5, 6, 7, 8, to 10 feet high. Standard, the finest Plants to be found in any Nursery. ALEXANDER, Hardy, of the best kinds, 3, 4, 5, and 6 feet high. The Plants referred to in this Advertisement have all been recently transplanted. Knapp Hill Nursery, Woking, Surrey.

GENUINE SEEDS ONLY.

ALL WHO HAVE A GARDEN should send their Name and Address for

BRINKWORTH & SONS'

CATALOGUE, Beautifully Illustrated, 3d. Post-free.

IT CONTAINS ALL THE

Choice and Popular Vegetable Seeds and New Potatos for 1882, at wonderfully low prices, carriage free.

Market Gardeners and Others will save 20 per cent.

BRINKWORTH & SONS, SEED GROWERS, READING, BERKS.

N.E.—A very fine stock of DAY'S EARLY SUNRISE PEA for Sale. Warranted true, 45s. per bushel.

GRASS SEEDS

FOR LAWNS,

Of the finest clover-growing Evergreen kinds, 1s. per lb. Special preparations for all purposes, soils, and situations. Advice gratis.

Unsolicted Testimonials:—

"Knowing how difficult it is to obtain pure stocks of grasses, even when price is a secondary consideration, I write to say the supply I obtained from you for our new terrace lawns has given the greatest satisfaction. "Please send me three bushels of the very best Lawn Grass Seeds, suitable for an exceedingly hot upland soil. The seed I have had of you has been the only one which has been able to resist the influence of the sun and drought upon my thin, gravelly soil."

FARM SEEDS

Of all kinds, which have given unqualified satisfaction. See Illustrated and Descriptive LIST, free on application.

RICHARD SMITH & CO.,

SEED MERCHANTS and NURSERYMEN, WORCESTER. (ESTABLISHED 1804)

NURSERYMAN, HAWICK, N.B.

ORCHIDS.

The Largest and Best Stock in Europe of good Established Plants. Tens of Thousands of Plants to select from.

MR. WILLIAM BULL

Begs to intimate that his Orchid-houses are always quite a sight, from the large number of plants in flower, and he will be pleased to show them to any one interested in this beautiful class.

MR. WILLIAM BULL

Recommends those desirous of having their Houses gay with Orchid flowers, to purchase good established well-cultivated plants, which bloom well, are far more satisfactory, and comparatively cheaper than newly imported or semi-established plants.

Establishment for New and Rare Plants, 636, KING'S ROAD, GREENSEA, LONDON, E.W.

POLYANTHUSES, PRIMROSES, HEPATICAS, and AURICULAS.

NATIVE GUANO,

SUITABLE FOR ALL CROPS.

Price, £3 10s. per Ton, in Bags, at Aylesbury.

A single cwt. Sample Bag sent, Carriage Paid, to any Railway Station upon receipt of Post-office Order for 5s.

This valuable Manure, prepared from Sewage by the "A B C" process, has been extensively used, for several years, by Farmers, Gardeners, and others, whose reports testify to its fertilising properties:—

EXTRACTS FROM LAST SEASON'S REPORTS:—

WILLIAM CRUME, *Gr. to Duke of Marlborough, Blenheim Palace Gardens, December 12, 1881.*

"Used for Vines, Peach trees, and other fruit trees, also Potatos, Carrots, Parsnips, Onions, &c. Results: satisfactory. Fruit trees assumed rich dark green foliage, increased vigour, whilst the fruit swelled up to a very fine size. Potatos came out in splendid condition; other roots too were benefited by its application. No other manure used with Native Guano. Undoubtedly a valuable fertilising agent, and I shall lose no opportunity of recommending it to gardeners and others."

A. BLAKE, *Head Gr. to H. Calverton, Esq., The Lilies, Woodon, January 3, 1882.*

"Used for Peas, Potatos, Onions, Cabbage, Cauliflowers, Celery, Vines, Cucumbers, &c.; Chrysanthemums, Primulas, Geraniums, Fuchsias, &c. Results: Onions, Cabbage, Cauliflowers, and Peas good; Cucumbers, first-rate. Potatos, a good crop, and I consider it a good manure for pot plants. I think the Native Guano only requires to be more known to the public to be largely used."

Sixteen Prizes awarded at Birmingham Show, 1881.

The Annual Show of Farm and Garden Produce, grown with Native Guano, will be held at Aylesbury in October next. Schedules and Prizes and all particulars, together with testimonials, &c., may be obtained upon application to

The Native Guano Company (Limited), Aylesbury, Bucks.

New Ready.

THURSDAY NEXT.

VALUABLE IMPORTED ORCHIDS.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY NEXT, April 6, at half-past 12 o'Clock precisely, by order of Mr. F. SANDER, St. Albans, a grand Importation of

CYPRIPEDIUM SPICERIANUM and C. SPICERIANUM MAGNIFICUM,

Just brought home by Collector. The variety magnificent has a very broad violet band and a distinct violet hue towards edge at back part of dorsal sepal, front being pure white with best very broad band. The lip is yellowish-brown, centre purple, the lateral sepals being much brighter than in the ordinary form and totally different colour. Collector states that they are yellow, with one or more purple stripes. The plants are in grand condition. See dried flowers.

PHALÆNOPSIS TETRASPIS.

We are pleased to be able to offer, at last, a really sound lot of this lovely Phalænopsis. Repeated efforts have been made to introduce it in a fine state; hitherto it has baffled all our energy—four consignments having arrived with scarcely a living plant among them. Those now offered have been brought home overland, under the care of Collector, and are sound and very fine.

AUCTION ROOMS AND OFFICES, 38, KING STREET, COVENT GARDEN, LONDON, W.C.

BOULTON & PAUL, Horticultural Engineers, NORWICH.

CONSERVATORIES, ORCHARD-HOUSES, PEACH-HOUSES, GREENHOUSES, &c. Illustrated Catalogue, Twelve Stamps; Illustrated Lists, Post-free.

Independent Slow Combustion Boiler for Small Greenhouses.

TO HEAT BY HOT WATER, REQUIRING NO BRICKWORK. Specially adapted for small greenhouses; for quick heating or slow combustion. Quite portable, and will heat properly for twelve hours. Made with strong wrought-iron cylinder set in a cast-iron base, with fire-bars and sliding door. Only one-tenth the cost of heating by gas, and much more effectual. Fitted with two 2-in. cast sockets, door for feeding, and socket for smoke-flue.

Cash Prices—Carriage paid.

of Boiler complete, as shown in illustration, but exclusive of piping—

Size.	Total Height.	Diameter.	To heat 4-in. Piping.	Price.
1	27 in.	16 in.	40 ft.	£3 10 0
2	30 in.	16 in.	40 ft.	4 0 0
3	33 in.	16 in.	80 ft.	4 10 0
4	36 in.	16 in.	100 ft.	5 0 0

Plain Saddle Boiler.

Plain Saddle Boilers are generally used for heating from 100 feet to 300 feet of 4-in. piping; above that quantity it is more economical to use our Check-end Boiler, as one of these, 3 feet long, will heat double the quantity of piping of a 3-foot Plain Saddle will.

Size of Sockets.	Size of Boiler inside arch.			Heating Power for 4-in. Piping.	Prices on application.

The Phoenix Slow Combustion Boiler.

We claim for our Phoenix Upright Boiler the following good qualities, viz.—It is made of the best materials; has no parts that are liable to failure; is provided with a flue that cannot be choked with fuel; will heat effectually the quantity of pipes stated with the smallest amount of fuel; can be easily regulated; and will hold fuel sufficient for keeping up the proper heat twelve hours; requires no brick work, and takes up the smallest space of any boiler of its power.

Sockets can be placed in any position.

Cash Prices—Carriage paid.

- WILLOW—Scarlet Palm, a Willow of extraordinary vigor. The bark of the young wood is of a deep purple-brown in winter, and it bears "lamb's tails" in spring of very large size. 4 to 6 feet, 3s. per dozen, 16s. per 100; 6 to 8 feet, 4s. per dozen, 20s. per 100; 8 to 10 feet, 6s. per dozen, 40s. per 100; 10 to 12 feet, 12s. per dozen.
- EUONYMUS—radicans argenteus variegatus, a very useful plant for edgings, must be cut, 5 to 6 feet, 2s. per doz., 12s. per 100; 4 to 6 in., 3s. per doz., 16s. per 100.
- ELDER—(Sambucus nigra) variegated: a beautifully variegated plant, which thrives close up to the sea; 6s. per dozen, 40s. per 100.
- .. cut-leaved—a handsome lacinated form, and, like other Elders, extremely useful for ornamental planting close to the sea. 6s. per dozen, 40s. per 100.

A slight extra charge must in most cases be made for packing. Where cash in payment of goods is sent with the order, the amount for postage may be forwarded in stamps after despatch of goods. All the above prices are subject to the discounts named at head.

THE GENERAL AUTUMN LIST
 will be forwarded Gratis and Post-free to all applicants.

N.B. Post-office Orders should be made payable to EWING AND CO., at Eaton, near Norwich. Cheques crossed GURNEY AND CO., Norwich.

Trade Terms on application.

THE
Gardeners' Chronicle.

SATURDAY, APRIL 1, 1882.

CUCUMBERS BY "EXPRESS."

AN express mode of growing Cucumbers! "Where?" "There," said our guide as he opened the door of a low small house, and almost pushed us in before him into a semi-suffocating atmosphere, filled with heat and reeking with steam. It nearly took our breath away, though we stayed long enough to note that the temperature was 95°, the air at the point of saturation, the plants strong and healthy, the leaves green and large, the fruit plentiful and in all stages of development, the largest being somewhat slim in girth to their length—most of them, however, being so straight and uniform in form as if they had been run in a mould, and all as crisp as glass and as green as Leeks. The sort, though, that, as explained, was immaterial to the system, was Tender and True, without doubt a very desirable variety. The soil was composed of rough pieces of fibry loam without any addition whatever—no, not so much as an atom of rotten manure, nor a handful of leaf-mould.

"I do not believe in mixtures," exclaimed our guide; "they may be all very well under slower methods of procedure—and there is no denying that good Cucumbers have been grown in the most extraordinary medleys of soil ever dreamt of; but mixtures are mere obstructives—absolute hindrances—and express modes of cultivation. Why, sir, before the roots have elected what to pick or choose out of the mixture, their opportunity for growth may have gone past recall. It is certain that they avail themselves of the pure loam at once. It is all of uniform quality, and the roots only concern themselves about permeating and exhausting it." The whole mass was so filled, overrun with roots, that hardly any soil was visible at the time of our visit. The surface was literally covered with a white network of white vigorous roots.

And yet we were assured the roots had been top-dressed less than a week before, and that so rapid was root-growth under express culture that top-dressing every week or ten days becomes a necessity. But the top-dressing was also peculiar. Instead of covering all the roots a few clouds of loam were scattered over the surface, hiding perhaps a half of them. Our guide assured us that he never liked to lose sight of his roots. He liked to see them to know what they were doing and what state they were in. Under the express system he assured us the roots were nearly always in sight: cover them to-day they are over the surface to-morrow. Besides he does not approve of covering them all at once. "Thin top-dressing and often" was his motto, also tentative dressings. Hence the surface of his soil was most irregular—a series of miniature mounds and dells. "At the next dressing the relative positions of the hills and the holes will be reversed."

These seemed small matters in details but the result was important: the whole of the root run was filled, and its entire surface whitened over with vigorous healthy roots. This

development and constant renewal of root force is much relied on in the express system. To our remark that his loam seemed poor our guide replied "No matter. It tends to the production of roots, and keeps them in a healthy state. That is all I ask of or from the loam. Give me roots in plenty and of sufficient size and vigour, and I will manage to feed them"—leading us towards a water-barrel, which he stirred up with an old mop, till from thence there arose such indistinct odours as might have drawn all the sanitary inspectors to the spot for miles round. "There," he said, "that is the liquid—true British guano—I feed them with; a strong half-and-half of pigeon-dung from the dovecot, and the other from cake-fed bullocks—cake fed, please to note. The barrel is emptied and re-filled every three weeks, and a quart of this, strong and clear, is added to each gallon of water given at the roots, the whole being applied at a temperature of 80°." "Nothing else—no nitrate of soda or other salts? The plants look so green that one would naturally think so." "No, no—nothing of that sort, nor artificial, nor salts of any kind, only the essence of the excrements named. Now, as to these, they never want for this, nor are they allowed to flag. Dry roots and dry air are fatal to express culture. We use evaporators or damp moss over the pipes, but chiefly depend for vapour and a deluging or vertical overhead plunge-bath every afternoon about 4 P.M.; after that, for an hour or two, you may almost see and hear the plants and the fruit grow. No matter if the thermometer reaches to three figures, it will not harm either the plants or the fruit. The oblique rays of the afternoon sun will neither scorch nor scald, but they can and do force growth in a most marked and extraordinary manner."

The growth, too, seems to continue all right, though the temperature may sink by dawn to 65° or 70°. The stimulus afforded by the extra heat and moisture in the afternoon and evening is like the momentum applied to carriages at rest on an inclined plane—they gather speed as they go, that enables them even to climb a steep hill at the further end of their journey. So it seems with Cucumbers grown by express. The accelerated growth at eventide carries them through the long night at express speed until the light and heat of the rising sun gives them a fresh push along the lines of growth and production. Light clean and strong is essential to this mode of culture; it gives the plants the vigour that enables them to stand up against the rapidity of their growth. But air is almost ignored; none is given during the earlier stages of growth, nor during cold weather. Of course this phrase, like so many more startling statements, covers a fallacy. No glass-house is air-tight. Besides, the greater the disparity between the internal and external atmosphere, the more like a sieve this heat-glass-house becomes; for the permeability of any closed structure to air may be said to be measured by the difference of the heat of its two sides. Hence, no doubt sufficient change of air takes place under express culture, though no ventilator be opened. But our guide has little faith in direct ventilation unless when excessive heat compels it, he gives none. He laughs at those who talk of air as food, and points to his extemporised mure tank. As for the air being exhausted, worn out, or rendered effete, he cares not, as long as he can see and feed plentifully his white network of roots.

Notwithstanding his vigorous growth, however, nothing is wasted. He boldly declares he does not believe in pruning Cucumbers. His plan is to lead all growth into productiveness. Hence no more is allowed to be made than is really wanted. Each shoot is stopped a leaf in advance of the fruit. By this simple

expedient the overcrowding of leaves and of shoots is prevented.

He is also careful not to overcrop, he assured us; though few visitors as they stood under the Cucumber roof, literally alive with fruit in all stages of growth, but must receive this grave statement with a smile of incredulity. We confess that for the moment we felt that after all the views of Cucumbers in fruit in the trade catalogues were not the exaggerations, born of puff, that they are generally assumed to be. The whole house seemed hidden with Cucumbers, young and old. No; there were no old ones, and herein lies one of the great secrets of success in Cucumber growing by express. The fact was, and is, the whole are cut when they get about three-quarters of their possible size. In that state they are far better to eat than when full grown; besides it is the last stage—the attempt, abortive or otherwise, to force or ripen seeds—that exhausts the plants, and the system of treatment adopted, though favourable to growth, is not so to maturation.

Under the express system seed bearing is indeed rendered impossible by the removal of every male blossom as soon as formed, and the fruit are cut before the exhausting stage of growth is reached. The result is that three Cucumbers at least are produced where one only would be grown under cool treatment, and it is claimed that the three are grown in a third of the time necessary to produce the one. But we dare not quote all we have seen or heard on the question of time saving by the express mode of culture. If one half that has been told in regard to this be true it would almost seem as if time or space would no longer be needed for the production of Cucumbers, but rather that they might be called forth by heat, moisture, and electricity as easily and rapidly as the transformations in fairy tales, or the Presto, change! of the modern juggler. With the most liberal allowances for exaggeration there can be no doubt that Cucumbers and other vegetable products are now produced in little more than a tithe of the time that they used to be. Without, therefore, assuming the responsibility of the so-called facts and statements advanced in this article we would invite the attention of our many practical Cucumber growers to them. We shall also gladly open our pages to short reports of what any of our readers have done in the way of Cucumber growing, and of the time that may have elapsed from seed-sowing to fruit cutting, and also the number or weight of fruit that may have been cut from a given area in a given time.

In this age of hurry and bustle, when even the importance of the husbanding of vital and other force and the conservation of energy are in danger of being lost sight of in a mere scramble and scurry, such facts and statements as these have a special interest and importance. Vegetable life is probably strong enough to take care of itself, and the more urgent and immediate duty of cultivators—a duty that becomes more pressing day by day—is how to force plants to produce the most produce of the highest quality in the least time and at the least expense.

THE THAMES.—Investigations undertaken by the City authorities show that even now the condition of the river is anything but what it should be. At Teddington there is little to complain of, but at London Bridge it was found to be "charged with sewage," the charge becoming greater down the river, and, of course, much more marked at the outfalls at Barking and Crossness—a sample taken at the former place on November 23 being reported to have contained one-fifth of its volume of sewage. Below these points the river becomes purer, till at Tilbury it is said to be practically uncontaminated with sewage. No fewer than 300 outfalls for sewage, it appears, still discharge into the river within the limits above mentioned. It is frightful to think of this continued defilement of a noble stream with all that that defilement implies, while the wasteful method of disposing of the sewage is indeed "a disgrace to our vaunted civilisation."

New Garden Plants.

ADIANTUM VICTORIE (*n. n. h. ?*)

The peculiar and distinctive features of this new Fern, which was exhibited at South Kensington on Tuesday last, and was awarded a First-class Certificate, are as follows:—

Habit dwarf and densely tufted; fronds ovate, bipinnate, with about one pair of compound pinnae, and four or five simple pinnae above; pinnales (or pinnae of the upper part of frond) bluntly conical from the straight or truncate base, or sometimes subrhomboidal, large, deeply lobed, the sterile lobes serrate, sori at the apex of the lobes oblong or reniform.

We have here a very distinct Maidenhair Fern, which will be invaluable for pot-culture for decorative purposes, and a most acceptable plant for the market grower. The plants exhibited, some half-dozen of them, were dense tufts about 4 inches high, and spreading to a diameter of 8 inches, the fronds densely packed, and forming close cushions of velvety-green, and we were informed that the parent plant is very little larger. The stipes and rachides are slender, wiry, ebeneous, and the general outline of the fronds shortly ovate, with a bipinnate mode of division. On the largest specimen before us, some 6 inches long, the lowest pinna, which has a clear stalk-like base of three-fourths of an inch, is 2½ inches long, and divided into five pinnales; the next pinna is barely 2 inches long, with three pinnales, and a shorter stalk; the rest of the frond consists of five large pinnales, of which the upper one is sub-rhomboidal, and measures 1½ inch in its longest, and 1 inch in its shorter axis, the others being long-stalked and nearly equal-sided with a straight-cut or truncate base and a short bluntly conical outline, the margin being deeply lobed, and the sterile portions of the lobes finely serrate. The sori do not appear to be very freely developed; in this case they occupy the apices of some of the principal lobes, and are usually oblong, sometimes reniform, or occasionally shorter, and almost circular. The young fronds are faintly tinged with red, and the whole aspect of the plant, dwarfed as it is, is strongly suggestive of young specimens of *A. farleyense*.

This novelty was raised by Mr. Bause, at the Melbourne Nursery, Anerley, and was shown by him on behalf of the General Horticultural Company (John Wills), Limited. Mr. Bause regards it as a possible hybrid raised between *Adiantum decorum* and *A. Ghiesbreghtii* (scutum), and there is considerable resemblance to the latter to be seen in the plant. The influence of *A. decorum* on the progeny, unless it be in imparting a dwarfer habit of growth, is not very evident; but, nevertheless, Mr. Bause fully believes in its hybrid origin, and the several distinct forms which he has originated—*e.g.*, *A. Bausei*, *A. Lathomi*, and now *A. Victorie*—certainly give some weight to his opinion, as it can hardly be supposed that all these should have been mere sports from the spores. However this may be, the *débutant* certainly will deserved the certificate awarded to it, as it will certainly be extensively grown. We have affixed to it, at Mr. Bause's suggestion, a name which at once is an estimate of its worth and an augury of the popularity which it will enjoy amongst Fern growers when more widely known. *T. Moore.*

ARUM PALESTINUM, Boiss.*

This fine species was, I believe, first introduced into cultivation by Messrs. Veitch & Sons, with whom it flowered in 1865, and from their plant it was figured in the *Horticultural Magazine*, at t. 5509, but probably it soon died out. Two years ago, however, it was reintroduced, and is now in the hands of Messrs. Heath & Son, Exotic Nurseries, College Road, Cheltenham, from whom I have recently received a specimen, and to whose kindness I am indebted for much of the information here given.

If I am right in the conjecture that the plant is not in cultivation from Messrs. Veitch & Sons' importation, it is somewhat surprising that it should be so, since *A. palestinum* is certainly one of the finest and

* *A. palestinum*, Boiss., *Diagn. sin.* p. 6; Schott, *Synop. Arid.* p. 5; *Prod. Arid.*, p. 79; Engler, in *DC. Monog. Phanog.* ii. p. 585; *Bot. Mag.* t. 5509.

most striking species in the genus, and as it is half hardy, easily grown, and the inflorescence, according to Messrs. Heath & Son, lasts from two to three weeks, and is scentless, it ought certainly to find favour with some; and there is no reason why it should not be used for decorative purposes, since, as it comes into flower about the same time as *Richardia ethiopia*, or at any rate could be made to do so, if mingled or grouped with that plant, its velvety-black inflorescences, which stand well above the foliage, would make a very effective contrast with the white inflorescences of the *Richardia*. No doubt if required it could be easily grown indoors as a window plant, only it will require to have a season of rest, during which it should be kept nearly dry.

At one time there was a craze to produce a black

11 inches long, tube obliquely campanulate, limb lanceolate, gradually attenuated to the acuminate apex, at first bent back and spirally twisted, afterwards opening out nearly flat; outside of spathe pale green on the tube, with some suffused purplish spots or blotches, dark dirty green on the limb; inside of spathe of a rich velvety black, except at the base of the tube, which is yellowish-white. Spadix considerably shorter than the spathe; ovaries light green, dark purple on and around the stigma; anthers very dark purple-brown; neuter organs black, subulate from a bulbous base, not rugulose, the lower series in from two to five cycles, the upper series in one or two cycles; appendix jet black, fusiform, subacute, with no distinct stipes, $\frac{1}{2}$ inch thick at the middle. Odour none. A native of Syria. *N. E. Brown, Herbarium, Kew.*

Joseph Hooker's *Rhododendrons of Sikkim Himalaya*, tab. xiii.

AZALEA SERPYLLIFOLIA, *A. Gray*.*

This is a low-growing species, with slender wiry branches covered with appressed lanceolate brownish scales. The leaves are small ($\frac{1}{2}$ — $\frac{3}{4}$ by $\frac{1}{2}$ inch), obovate apiculate, tapering to a short stalk, dark green above, paler beneath, with only two or three pairs of primary nerves, and thinly sprinkled with simple appressed strigose hairs. The flowers are in terminal tufts, each with a very short pedicel covered like the ovary with shining white scales, and springing from the axil of deciduous brownish setose scales. Corolla white, about $\frac{1}{2}$ inch in diameter, rotate, with a very short glabrous tube and a fat limb with five oblong, somewhat irregular lobes. Stamens five, about the

FIG. 65.—RHODODENDRON PENDULUM: FLOWERS WHITE.

Hollyhock; but here is a plant ready made with an inflorescence as black as any one could wish for. As *Arum palatinum* has never been fully described, and has been placed in a wrong section of the genus by both Schott and Engler, by which one is apt to be misled in determining this species, as I was at first myself, I here give an amended description of the plant.

The tuber, according to Messrs. Heath & Son, is long, flat at the apex, not perceptibly different from that of *Richardia ethiopia*. Leaves four or five to a plant, petioles 12 to 18 inches long, stout; lamina triangular-hastate, acute, a little constricted just above the basal lobes, which are half as long as the front lobe, ovate-elliptic in outline, and very obtuse; the lamina varies in size from 6 to 14 inches in length, and from $\frac{3}{4}$ to $7\frac{1}{2}$ inches in breadth, dark glossy green above, paler beneath. Peduncle longer than the petioles, sometimes rising 8 or 9 inches above the leaves, pale green, terete, $\frac{1}{2}$ inch thick. Spathe 7 to

RHODODENDRON PENDULUM (fig. 65).

By the side of the magnificent trosses of *R. grande* (argenteum), recently shown by Mr. Mangles, this little species may seem to some insignificant. A true plant-lover will not acknowledge any such adjective, however, and many a cultivator whose space at command is not sufficient for the larger kinds, may be glad to grow this. In its native country, Sir J. D. Hooker describes it as pendulous from the branches of tall Silver Firs, such as *Abies Webbiana* and *Brunonia*, growing in gloomy forests, at an elevation of 9000—11,000 feet. It may possibly be hardy here, therefore, in sheltered situations. The foliage, as will be seen, is not unlike that of *R. ciliatum*, ciliate but never scaly. The corolla is white, regularly bell-shaped, with fine spreading obtuse lobes. Our illustration was taken from a specimen obligingly put at our disposition by Mr. Mangles, who has so successfully cultivated the plant that its blossoms are nearly double the size of those figured by Fitch in Sir

length of the corolla, filaments glabrous, anthers minute, purplish. Style white, exerted.

This forms a charming little bush for a rockery or fernery under glass, its dwarf straggling habit, neat foliage, and pretty white flowers rendering it suitable for such purposes. Probably in the south and west it might be found hardy. The plant from which our notes were taken was shown by Messrs. Veitch at a recent meeting of the Royal Horticultural Society. Botanically, it falls into the genus *Rhododendron*, and into the section *Tusia*, to which the Indian *Azaleas* belong, on which account and for general convenience and garden purposes we retain the name originally proposed by Asa Gray of *Azalea serpyllifolia*. *M. T. M.*

* *Azalea serpyllifolia*, A. Gray, ex Maximowicz, *l. c.*, et in Herb. Kew: *Azalea serpyllifolia*, hort. Vench: *Rhododendron serpyllifolium*, Miq., *Prodr.*, p. 57, ex Blasimowicz, *Rhod. Asia Orient.*, Mem. Acad. Imp. Sc. St. Peterb., 1870, p. 42 (S. Tusia).

STANSTEAD PARK NURSERY.

THIS well-known nursery establishment, the property of Messrs. John Laing & Co., which has long been famous for its collections of florists-flowers and general nursery stock, is easily reached from Forest Hill station on the Brighton line, and from which it is distant but a few minutes' walk. The nursery also enjoys the advantage of being located a healthy distance from the noxious vapours proceeding from the metropolis, and it enjoys the further distinction of being within short distance of the Crystal Palace, where visitors from all parts of the globe find their way at some time or other during the season. But the nursery is not, indeed, dependent upon extraneous attractions to render a visit to it interesting or enjoyable at any period of the year. It is an establishment in which great numbers of the most popular plants are grown, including tens of thousands of the single and double tuberous-rooted Begonias, for which the nursery is now celebrated. The nursery, too, like the roots of a healthy tree, is ramifying, and extending itself in other directions. There are the branch establishments, Rutland Park, where ornamental shrubs, fruit trees, and Roses, are grown, and "The Vineyard" (the latest addition to the Messrs. Laing's business), where Grapes, cut flowers, Grape-Vines for planting, and fruit trees in pots are grown in large quantities. Such important additions, in what are commonly called times of depression, speak for themselves.

Returning, however, to the parent nursery in the Stanstead Road, the visitor will find the seed warehouse and other offices within the gates of the nurseries. The glass-houses occupy a clear open situation at the back of these, and are of modern construction, affording abundance of air and light to the thousands of plants which they contain, all of which are, from the nature of the system, under which they are cultivated in the best of health. One could not indeed even mention the different species of plants which are here so well represented, but it is noticeable that popular favourites are everywhere predominant—tree Carnations, a whole house of them; the charming *Alcagatère*, so favourably known for winter flowering; also *La Belle*, *Gloire de Nancy*, *Souvenir de la Malmaison*, *Miss Jolie*, and, among a great many others, *Favonia*, a beautiful variety for cutting, being a free bloomer, with delicate lilac stripes in petals of pale rose. A half specimen of the variety *Alcagatère*, with short sturdy growth, proves what can be done with these plants by cultivation. Zonal Pelargoniums and forced Roses are grown in a span-roofed house without rafters, where it is needless to say, they are in fine condition; and a few miscellaneous plants are dotted about by way of giving variety, among which plants of *Begonia recurva* have a good effect. What charming plants these are for house furnishing, and how seldom we see them used. I may just mention the stock of bronze and tricolor Pelargoniums, occupying a whole house by themselves, with which Mr. Laing's name has been so long and so successfully identified. Why have we turned the cold shoulder upon such lovely plants?

The collection of Camellias, Azaleas, and New Holland plants will be found very interesting upon inspection. The house in which they are arranged is a large span-roofed structure, the tall Camellias and Azaleas occupying the centre stage. Other plants of interest comprise a collection of the beautiful *Azalea mollis*, *Erostemon pulchellum*, *Taconias* (in suitable sizes for planting out), *Boronia teranora*, specimen hard-wooded Heaths, small plants of *Erica perspicua* nana, *Acacia lophantha*, *Eurya latifolia*, and many others. On the south side of this house there is a block of seven span houses, running east and west. No. 1 is the famous *Begonia*-house, which was under repairs at the time of my visit. No. 2 contains a general assortment of plants, comprising *Stephanotis floribunda*, *Bomarea Cardeii*, a large batch of *Areca speciosa*, *Tuberoses* in quantities, *Begonia undulata*, and other plants suitable to meet the demands of the day. The third house of the block is an important one, being filled with a grand collection of Palms, consisting of very fine specimens of *Areca lutescens*, *A. Verschaffeltii*, *A. sapida*, *Lantana borbonica*, and good supplies of *Jacaranda mesocephala*, *Fassioflora quadrangularis*, *Cleorodendron Balsamiflorum*, *Cissus discolor*, *Bougainvillea glabra*, *Lapageria alba* and *rosea*, *Couypha australis*, and others. No. 4 is filled chiefly with

Ferns, of which *Adiantum cardiophyllum* is very fine, as also *A. Basei*, *A. Hendersoni*, *A. fulvum*, *Davallia Mooreana*, *Selaginella cæsia arborea* (the tree moss), and other interesting subjects of the same genre.

House No. 5 contains over 40,000 young plants of tuberous-rooted Begonias, and, as showing the immense demand that the Messrs. Laing have for these plants alone, it may be mentioned that over 100,000 young plants have been already pricked off this season. But still better things are expected, and a richer display and greater variety of colour is confidently looked forward for in this lovely class of plants than has at any former time been brought under the notice of the horticultural public. So much for quantity, but the reader may inquire which are a few of the prettiest and latest novelties. Of singles the Hon. Mrs. Brassey (intense crimson), *J. W. Ferrand* (bright vermilion), *Arthur G. Snares*, *exoniensis*, *Mrs. Robert White*, and *Scarlet Gem* will be found exceedingly handsome; and of doubles *Bernice*, a variety bearing immense crimson flowers; *Clovis*, *Davis*, *hybrida fl.-pl.*, said to be double as a *Kanaculus*, *Dina felix*, *Duchesse de Cambacérès*, *Duchesse de Galiera*, *Eugène Lequin*, *Gloire de Nancy*, *Louise Bochet*, *Madame Renard*, *Marie Bochet*, *Marie Lambert*, *Wm. Beatty*, *Dr. Duke*, *Glory of Stanstead*, and *Mrs. Captain Thomson* are among the latest and finest novelties. *Caladiums* are only second in importance to the Begonias in this establishment, and of these *Anna de Condeixa*, *Candida* (which obtained a First-class Certificate at the meeting of the Royal Horticultural Society on June 14, 1881, and also at the Royal Botanical Society on July 6, and is said to be a splendid variety), *Cardinal*, *John K. Box*, *Salvator Rosa*, *Souvenir de Madame de Bernard*, *Ludemann*, *Sanchoanathum*, and *Verdi* are among the very best.

The next house contains a large stock of *Phoenix rupicola*, *Areca* in a young state, and *Cocos Weddelliana* by the thousand. Also *Asparagus plumosus nanus* and *Codium Irvingii*, certificated at South Kensington and Regent's Park last year—a long narrow-leaved variety of a bright golden-yellow suffused with crimson. Another novelty worthy of mention is *Illya glabrosa Hugginii*, certificated in April, 1880—a very handsome species with large thick leaves, and bearing flowers of a bright scarlet colour which are freely produced. *Lantana rubra* and *aurca*, *Cyperus laxus* and *Begonia metallica* are shown in quantities in the same house. The stock of show and fancy Pelargoniums and Azaleas, in fine health, fill a whole house of themselves, and no better examples of cultivation could be desired. The plant stove contains a well grown collection of stove plants and Orchids, *Palms*, *Dæceas*, *Aralias*, *Fitcher-plants*, *Anthurium Waiocuanum*, with immense leaves and in grand health, as indeed may be said of the whole collection. Other specimens, especially well grown, are *Campylobotrys Giesbreghtii variegata*, *Medinilla magnifica*, *Anthurium crystallinum*, *Curcigo recurva striata*, *Phenacophorum sechellarum*, and *busts* of others; while a mixed house is filled with *Palms*, *Ficus*, *Gloxinias*, and *Lilies of the Valley*. By-the-way, the Messrs. Laing have a large stock of *Gloxinias*, and I will just mention half-a-dozen of the finest named kinds, viz., *Duke of Albany*, *Eclipse*, *Leviathan*, *Rehnetem*, *Queen of Koses*, and *Queen Victoria*.

From the stove the visitor proceeds to the *Cineraria*-house, a structure unusually interesting at present, owing to the fine display of double *Cinerarias* which it contains. The plants are healthy and well grown, and in a short time will be at their best. The sorts that struck me most are *Chad Valley Beauty*, *Rowena*, *Mr. Thomas Loyd*, and *Fairy Queen*. No one can really form a just and accurate estimate of these plants until—to use a common phrase—the flowers are full-blown, at which period only they are seen in their full beauty. Heated pits are filled with *Solanums*, soft-wooded Heaths, *Genistas*, *Lachenalias*, *Hollyhocks*, *Pelargoniums*, and *Cytisus*, while hardy plants in cool pits and plunged out-of-doors may be counted to infinity. These comprise *Clematis*, *Tea Roses*, *Charles X. Lidacs* for forcing, and *Syringa rubra* de *Morley*, the French forcing *Lilac*; *Carnations* and *Picoetes* (all *Dodwell's* best), *Chrysanthemums*, *Pentstemons*, *Pansies*, and herbaceous and alpine plants generally in all the leading varieties. The novelty of the season in *Pansies* is *Master Ralph*, and of *Carnations*, *The Governor* and *W. P. Miner*.

The *Vineyard*, lately acquired by Messrs. Laing & Co., lies between Perry Hill and Calford Bridge Station, and is less than 5 minutes' walk from Stan-

stead Park. The glasshouses here are extensive, consisting of four ranges, each 150 feet long. The Vines that are planted out have done remarkably well, and include the staple kinds for yielding a supply of Grapes through the greater part of the year, viz., *Hamburg*, *Muscata*, *Alexandria*, *Madresfield Court*, and the favourite late black kinds. *Strawberries* are successfully forced, and in large numbers; *Figs* are fruited in pots, and several thousands of *Grape Vines* are grown from eyes this season, and a healthy promising stock they look. A general stock of fruit trees in pots and saleable Vines in variety are also in stock and in excellent condition. One of the ranges is exclusively devoted to *Rose* growing, in which every variety that is worth growing for supplying cut flowers in the winter and early spring finds a home, and a congenial home too, if one may form a judgment from appearances. The rambling kinds, such as *Marchal Niel* and *Gloire de Dijon*, are trained upon trelliswork, and the dwarfier growing kinds are planted out in the borders. *Niphetos* and *Madame Falcot* are two favourite kinds for supplying buds. Anent *Roses*, I may add that a plot of ground is being deeply trenched and heavily manured in which *Tea Roses* are to be planted out and which are to be covered in with heated pits in order to obtain a supply of *Rose buds* in winter when other sources fail to supply them. In addition to the stock already mentioned in this branch propagating and plant growing is also carried on of *Marguerites*, *Grevilleas*, a grand stock; *Primulas*, an excellent market strain; *Cinerarias*, *Aspidistra lurida variegata*, *Richardias*, *Palms*, &c.

The Rutland Park nursery is, as has been already stated, set apart for the cultivation of choice Conifers and other ornamental shrubs, fruit trees, *Roses*, and forest trees. There are acres of pyramid *Pears*, "double worked" *Apples* and all other kinds of fruit trees in greater or less quantities. Trained *Peaches*, *Apricots*, and *Nectarines* are exceedingly fine—one-year-old cut-backs with from five to seven shoots to each, models for wall training. *Roses* and *Rose stocks* are counted by their thousands, some in dormant bud, others ready for planting; of the former the stock of *Belle Lyonnoise* and *Gloire de Dijon* is unusually vigorous and promising. Messrs. Laing have a *scuteler* for dressing *Brier stocks*, which I believe is not commonly used. It is fitted into a framework standing upon four legs, and works by cog-wheels which gives the instrument great power and enables an ordinary handy workman to dress 1200 stocks in a day (figured at p. 72 of our volume for 1872). The best appliances are used in this nursery by competent workmen, yielding results which cannot fail to be satisfactory to all concerned. *Reporter*.

THREE INTERESTING PLANTS FROM BRITISH GUIANA.

It is a collection of dried plants made by Mr. G. S. Jenman in British Guiana, and sent by that gentleman to the National Herbarium at Kew in January of this year, are contained many interesting plants, and among them a fine specimen of the plant described by Mr. Baker from imperfect material in the *Gardeners' Chronicle*, 1880, vol. xiv., p. 243, as *Cordylina micrantha*, but which, now that more ample material has come to hand, turns out to be, not a *Cordylina* at all, and which does not even belong to the order *Liliaceae*, but to the *Bromeliaceae*, and is thought to belong to the little known genus *Brocchinia*; it will, I believe, shortly be fully described by Mr. Baker under the name of *Brocchinia cordylinoides*, along with another new *Bromeliad* contained in the collection. This fine arborescent *Bromeliad* is represented in the foreground of the illustration that accompanies the description on p. 241 of the volume of the *Gardeners' Chronicle* above quoted. It appears to be confined to the savannah above the Kaieteur Fall in the Potaro river, and is inhabited by another very handsome and interesting plant, viz., *Utricularia Humboldtii*, which finds a home in the water held in the axils of the leaves of the *Bromeliad*. Mr. Jenman states on the label sent with the *Utricularia* that it is "aquatic, confined to the water contained in the axils of the leaves of *Cordylina micrantha*, which is always copious. The stems rise up and flower above the leaves of the *Cordylina*. Very common. It appears to be strictly confined to the *Cordylina* [*Brocchinia*]."

If the *Bromeliad*—together with its dependent, the *Utricularia*—could be successfully introduced into cultivation they would form very striking and interesting objects. *Utricularia Humboldtii* is very different in appearance from either *U. montana* or

U. Endresii, and is one of the finest species of the genus; the petioles of its leaves are from 1½ to 2 feet long; the leaf-blade is cuneate-reniform in outline, and from 2 to 5 inches broad; the flower-stem apparently grows to about 3 feet in height, and the flowers are about 1½ inch in diameter.

Mr. Jenman's remark, that it appears to be strictly confined to the Iromelid, may be correct, so far as that region is concerned; but Schomburgk, who discovered *Utricularia Humboldtii*, states, in his *Races in British Guiana*, p. 1086, that he collected it on the southern declivity of Roraima at an altitude of 6000 feet, growing in boggy grassy places along with *Helleophora*, *Cypripedium*, &c.

Another plant contained in the collection that appears to be of interest is one of the *Gesneriaceæ* (No. 1067, *Codonanthe*, sp.?) which, according to Mr. Jenman's note, he found "growing in ants'-nests upon bushes and trees." Is this really the case—that is, does the plant grow in the earth which the ants have carried up into the trees to construct their nests with? Or can this be one of those interesting plants of which certain ants make use of the base of the stem for a nest, making galleries through it in all directions, and causing an enlarged development of that part of the stem, so that it resembles a tuber traversed by sinuous passages, as in the well-known cases of *Hydnophytum* and *Myrmecodia*? In fact, does or does not the ants' nest in this case form part of the plant? The specimen does not show this, and the question is worthy of inquiry, as I believe that no ants'-nest plant of this character has yet been recorded as occurring in America. *N. E. Brown*.

GLADIOLUS.

Of all so-called bulbous plants *Gladiolus* are, I think, the most showy and beautiful, sending up, as they do, long spikes clothed with lovely gay flowers. For growing in beds and borders they are quite unrivalled, and they are equally valuable for pots, as they may be got on early, and they come admirably for dropping in among other plants on a stage, where a few of them brighten up a whole house by their presence. One of the most showy among them is the old *G. brechleyensis*, the blooms of which are of a large size and fiery scarlet in colour. Corms of this kind may be had at a cheap rate, and if potted or planted at once will make a grand display in the autumn. The finest, however, that can be obtained are the hybrids that have been raised from the above-named, which embrace almost all shades of colour, the delicate ground and the superb markings of some being rich in the extreme. Spikes of these are simply magnificent, and the numerous varieties of *G. gandavensis* are also very showy and well adapted for border work, and if planted at intervals from now till the middle of May will yield a long succession of bloom. The earliest flowering kinds are those of the ramosus section, which are much dwarfier than the others, and so hardy that they may be left undisturbed in the ground, where, if the soil is light and suits them, they gain strength, and flower with great freedom. For affording cut blooms these sorts are invaluable, as, the spikes and blossoms being small, they are just the thing for vases, where they dress well, and last long in water.

The best way to grow the different kinds of *G. ramosus* outdoors is to prepare a narrow border or bed in a warm, sheltered part, and there plant the bulbs, and allow them to remain undisturbed. To ensure them against decay there is nothing like sharp sand, a good sprinkling of which should be scattered over the corms before covering them up. Managed in this way, the soil does not come in immediate contact with them, and they remain snug and dry for the winter, as the water cannot lie, but drains freely away. To keep out frost, leaf-soil is the most serviceable, as it lies light, and acts as a top-dressing without shutting out too much of the air, or souring and injuring the soil. If grown in pots, a purpose for which the ramosus section of *Gladiolus* are specially adapted, the pots should be well drained, and from three to five corms placed equidistant in each 6-inch pot, and covered about 2 inches deep. Sandy loam that has been well enriched suits them the best, and when potted they should be stood in a cold pit or frame, and kept without water till the leaves begin to appear, when they should have just enough from time to time to keep the soil moist. When the pots get full of roots liquid manure will

be a great help, and will enable the plants to push up fine heads of bloom.

The hybrids of *G. gandavensis* and *brechleyensis* being so much larger, require bigger pots, if more than one are grown together; but if singly, 6-inch pots are sufficient. The same kind of soil, potting, and treatment recommended for the others will suit these; but the thing with both, after flowering, is to avoid them every encouragement to form and mature their corms. This may be done by plunging them in ashes or other material out in the open, where they can be duly attended to with water, so as to keep the foliage healthy and green till the time comes for it to ripen and die away naturally when no longer of use to the roots. When grown in beds or borders it is necessary to trench the ground deep, but in doing this the subsoil should not be brought to the top, but have plenty of manure worked in, which answers better than having it nearer the surface, as *Gladiolus*, being planted deep, would be injured by touching it. In cases where the soil is heavy and unsuitable, it is a good plan to dig out holes in borders and refill them with turfy trimmings from the roadside, in which material *Gladiolus* always do well.

The way they look best and make the most show is by planting three in a patch at about 6 or 9 inches apart, and in beds, the rows a foot from each other, and the same distance from plant to plant. The spikes being very heavy, when in flower they should be securely staked and tied, or the wind will soon carry them over. The proper time for lifting *Gladiolus* is towards the end of September, but it is a mistake to dry and store them quickly, as some do, as by so doing they sustain much loss of vital power on account of the corms shrivelling before they are ripe. Instead of the drying process it is much better to place them in pots of sand and stand them in a light house or pit where the tops can die away slowly. The sand, too, is good for them to winter in, as it keeps them in a more uniform condition, and corms stored in it will always be found more plump and sound in the spring. The place for wintering should be very cool, as otherwise roots are formed before they ought to be emitted, and get injured or destroyed in the moving and planting. *J. Sheppard*.

THE VEGETABLE PRODUCTS OF PARAGUAY.

THE following notes, gathered from a recent report by Mr. E. H. Egerton, on the above subject, will give an idea of the character of the economic plants of that country. Paraguay, we are reminded, is but very slowly recovering from total collapse, the result of the depopulation and financial ruin caused by its great war. Two sugar-mills are reported to have started work. The Paraguayan sugar-cane is said to contain more saccharine matter than the Tucuman cane. On this subject, however, Mr. Egerton says:—"Though my opinion is not worth anything, the rich alluvial soil of Tucuman seemed to me more suitable for the cane, which certainly grows thicker and more luxuriantly there than in the Paraguayan red sandy soil, fertile though the latter be.

"Paraguay will find it hard to find a market for her sugars, as in Monte Video and the Argentine Republic there are heavy import duties, so that I cannot believe much production of sugar, beyond that for home consumption, will take place in Paraguay."

Tobacco is grown everywhere, but the better quality comes from near Villa Rica. Cigars prepared like Havanas are made there, and there may be considerable increase in the export of these. The taste of nearly all Paraguayan Tobacco is somewhat strong and bitter, which will prevent it fetching high prices. Of undressed Tobacco large quantities are sent to Bremen and other ports of Europe from Asuncion, *via* Buenos Ayres and Monte Video.

Of oil from the indigenous *Coco Palm* a fair quantity is made. There might be a considerable increase in this article, as there are vast quantities of this tree in the neighbourhood of Asuncion. A quantity of ground-nut oil is produced. It is known as "Mani." It is used as a substitute for Olive oil. The Castor-oil plant, which grows well in Paraguay, is recommended for more extended cultivation in consequence of the oil being valuable for lubricating purposes.

Enormous quantities of Oranges are sent from Asuncion to Buenos Ayres, Paraguay having a reputation for the excellence of its Oranges, which are much superior to those of Corrientes. Most of the

gardens contain Banana trees, and there is some export of the fruit. Coffee is grown on a small scale on the northern side of the hills; its flavour is very good, though somewhat strong and bitter. No Wheat seems to be grown, but the native bread, made from the *Mandiocora* root (*Manihot utilissima*), an excellent and wholesome substitute. At present, the newer valuable produce of the country is the Yuba Maté (*Ilex paraguayensis*), of which increasing quantities are yearly exported. The Paraguayan Maté, though better than the Brazilian, is not equal to that of the Upper Argentine Misiones.

The wealth of timber is immense, all the hills—and the whole country is hilly—being covered with splendid trees, and all the marshy shores of the Paraguay are a vast forest. When more *Isaques* and *Italians* arrive the timber trade may become important, and barges full of valuable hard woods may be floated or towed down the river for export. Such hard work as felling or dressing trees is not very congenial to the native Paraguayan.

Of medicinal plants "Jaborandi" (*Holcarpus* sp.) is referred to as being one of the most important, and a plant, of which the native name "Yambayú" alone is known, is considered by the Indians as a cure for asthma. *Ipacacanha* is grown in large quantities, but it is said to be distinct and inferior in quality to that from the Brazilian province of Matto Grosso.

Of dyes that obtained from *Eupatorium tinctorium* is said to be very similar to indigo, though perhaps a little darker. It is a very good dye, and is the blue colour that has long been in use by the Indians. A small sample of this dye lately sent to France for trial is stated to have realised 12 francs, when Indian indigo was sold for 15 francs. The Central American blue dyes have generally been beaten from the field by the Indian indigo; it seems, however, that this Paraguayan shrub is so remarkably prolific and vigorous that it can be stripped of its leaves four times a year without injury to the plants. As it requires but little care or cultivation this dye plant may some day compete in the European market with that of Indian indigo.

Regarding fibre plants there are many that yield large crops and fibre of good quality. "But," Mr. Egerton says, "by far the best fibre of the country is that of the *Caragatá ibérica*, a *Bromeliaceæ*, which is something like the Pine-apple plant, and which is very abundant in Paraguay, the Misiones, and the Chaco. It is very long and silky, and has long been used by the Indians, and much money has already been spent in endeavours to find some practical machine for the economical preparing of this fibre. I am assured that the desired result has now at length, after a long series of experiments, been attained by a French machine, invented for the purpose, which has just been set up not very far from Asuncion, the process being a simple one without previous maceration. Should this invention prove a success the *Caragatá* fibre will become an extremely important article of export, and if half I hear of it be true should compete with advantage against Jute. I am assured, but I cannot vouch for the assertion, that there is immense superiority in the quality of the Paraguayan fibre over that of the Chaco and Misiones *Caragatá*."

This plant is referred to in the *Kew Report* for 1877, p. 37, as a paper material upon which Mr. Routledge had remarked that "Fibre when abstracted no doubt will make good paper." It is also stated in the report to have been determined at *Kew* to be "one of the singular South American species of *Eryngium*, which have before flowering quite a *Bromeliaceous* habit." *J. A. J.*

SHADING ORCHIDS.

THIS is a subject of the greatest importance in Orchid culture, and one that is often overlooked until it is too late—the mischief being done. What is required is a strong durable material that will wear well, and, where rollers are used, stand the strain upon it. It must also be understood that shading does not consist of merely daubing upon the glass some opaque material, such as paint, "summer cloud," whitening, or the like, which, though all very well as palliatives in positions where rollers cannot be used, such as at the ends and sides of a house, are greatly to be deprecated as a shading for the roof, for this reason, that in our English climate we are so subject to sudden changes of the weather that were such a permanent shading to be used we should frequently—

especially during dull weather—have our plants in comparative darkness when they should be getting all the light possible. This cannot fail to lead to bad results, and produce a sickly growth.

Some growers use thick canvas; indeed we have done so ourselves many years ago, but, by experience, we have found out the ill-effects of it, for when we employed this kind of shading we found the plants under its influence became weak and sickly, producing small puny flower-spikes. A lighter shading was then employed, and the difference was marvellous; the plants assumed quite a different aspect. It was at this time that we were exhibiting at Chiswick the fine specimens of East Indian Orchids—*Aerides*, *Saccolabium*, *Vandas*, *Dendrobium*, and many others—such as we seldom see equalled now. Since then we have used thinner shadings with the best results. Our *Vandas* thus treated have always been strong and healthy, with broader foliage, producing their flower-spikes as often as three times a year, with the flowers of a good colour, lasting a long time in perfection; in fact we are never without flower, always having a good display. We refer more particularly to the *suavis* and *tricolor* section of the genus. Some people imagine *Vandas* do not flower till they attain a large size, but such is not the case if they are properly grown, and thin shading is used.

Our experience leads us to the belief that all Orchids, with a few exceptions, require a thin shading—that is to say, one that, while warding off the direct rays of the sun, will allow the light to enter through it. To arrive at this result we use a strong, durable, cotton netting, woven in small squares, close enough to exclude the rays of the sun, while the light penetrates it with but little interruption. This netting stands exposure to the weather much longer than canvas, and on that account is cheaper in the long run. We have used this material for some years; in the case of cool Orchids, Mexican, and East Indian kinds, with the best results, the netting being attached to rollers with appropriate gear. For the cool Orchid houses we employ raised blinds, upon which we hope to speak further shortly. The blinds can be managed with but little trouble. In the winter we take them off the house and put them in a dry place until they are required again in the ensuing spring. *E. S. Williams, in the "Orchid Album."*

AN AGARICUS-BOLETUS.

SEVERAL references have been made of late years in the *Gardeners' Chronicle* to the occasional curious abnormal resemblance of some fungus to another fungus of a totally different order or even family. Such was the case in the remarkable example of *Agaricus furfuraceus* mentioned in the *Gardeners' Chronicle* for March 4. Resemblances of a similar nature may be useful to some animals and plants, but we cannot see that any good end is served amongst fungi. A great number of *Agarics* extremely resemble in colour the dead autumn leaves amongst which they grow; other examples, less common, stand out in contrast against the brown and russet dead autumnal leaves. A recent sharp observer, Mr. C. B. Plowright, has called attention to the fact that Mushrooms, by their white tops, stand out in strong contrast against the green pasture grass; he indicates no benefit to the plant in this, but if Mushroom spores are really benefited by passing through the stomach of a herbivorous animal—which some persons assert, but which we greatly doubt—the fungus is clearly benefited by its colour attracting the ox or sheep to eat it [while the Mushroom-loving bipeds can the more easily find materials for their *ragouts*. Ed.].

One of the commonest funguses of hedge-sides and open places in woods is *Paxillus involutus*, illustrated in the upper figure of fig. 66. It is deep yellowish-brown in colour all over, clammy to the touch, of the shape shown in the illustration, and in every way a "regular Toadstool." It belongs to the order *Agaricini*, and therefore in typical examples the under-surface of the cap is (or should be) furnished, as in the Mushroom, with gills radiating from a central stem. Fungologists have noted that in some examples, but by no means in all, the gills of this plant anastomose near the stem and form little pores of a *Boletus*-like character, as shown at base of the gills in the upper figure. Sometimes these pores occupy one half the space of the gill-surface and the fungus at once becomes half an *Agaricus* and half a *Boletus*, these two genera being members of two widely separated orders. But as far

as we know, no one has yet called attention to the fact that the under surface in *Paxillus involutus* is sometimes wholly porous and in every way a true *Boletus*, as in the lower of the two figures, *b*. In some districts this *Boletus* form is quite frequent, and we have many times had it sent on to us as a *Boletus* not to be found in fungus books. The fungus therefore is clearly sometimes an *Agaricus* and sometimes *Boletus*. The Rev. M. J. Berkeley, who has written so much and so exhaustively of fungi, says of this plant in the *English Flora*, 1836, p. 101, "The gills of this species separate from the pileus like the pores of a *Boletus*." This is of course quite true, the gills naturally separate from the pileus because (as in *Boletus*) there is no trama, so that Fries in his *Eporis*, 1836-8, p. 315, removed the plant from the genus *Agaricus* and termed it *Paxillus* with the generic character of "Trama in genibus nulla."

No question is more frequently asked by beginners in fungology than "What is a trama?" The trama

FIG. 66.—PAXILLUS INVOLUTUS.

can easily be explained by the two lower outline figures of fig. 66. Both represent part of the cap of a Mushroom with a slice obliquely cut off showing the gills in section. The upper of these two outlines, *c*, shows a fungus with no trama, and the lower outline, *d*, a fungus with a trama. The trama is the part of the flesh in the immediate centre of the gills, so that when the skin of the gills is peeled off (not always an easy piece of work) the inner substance of the gills (trama) is left exposed like a second and internal series of gills, *d*. The trama is shown at *e*. The section at *c* shows a fungus with *Paxillus* characters, and here it will be seen that if the gills are peeled away the under-surface of cap will be left quite plain, as in *Boletus*, for there is no trama or inner substance of the gills. Nyländer and Hofman say they have seen a trama in *Paxillus involutus*.

No doubt the presence of a trama is an important character in the higher fungi, but it is an unfortunate

fact for systematists that some *Agarics* have a trama when growing in some positions, and are totally without one in others. Such is the case with the edible *Agaricus peronosatus*. This species ought to have a trama to suit the views of writers on books about fungi; it commonly has a very decided trama, but it is equally certain that it is frequently without one. Sometimes this plant, then, is an *Agaricus*, and sometimes a *Paxillus*, and *Paxillus* in its turn is capable of becoming a genuine *Boletus*. Fries saw this difficulty, and in his elaborate *Monographia Hymenomycetum Suecicæ*, vol. iii., p. 310, advocated the placing of *Agaricus peronosatus* under *Paxillus*. But then a good *Paxillus* should have red spores, whereas *Agaricus peronosatus* has white ones. Fries therefore put it under a section of *Paxillus* named *Lepista*, a small company with dirty white spores. Such a state of things seemed very incongruous, so the writer of this notice once proposed that *Lepista* should be a genus instead of a sub-genus; and so *Agaricus peronosatus*, *alias Paxillus peronosatus*, became for a time *Lepista peronosata*, and at this time so stands in Cooke's *Handbook*. But Fries, in his latest work on Fungi, replaces this *Paxillus* or *Lepista* in its old place in *Agaricus*. Fries deserves great credit for this; he knew he was not above error, and he was not ashamed to confess that his views in 1874 were not quite the same with those of 1838. In original scientific work it does not follow that because a man thinks a certain thing at one time, he must of necessity think the same thing at another, or indeed that any original observer thinks and believes to-day exactly as he did yesterday.

Now if we return to *Paxillus* and its trama, and take up another species, as *P. patouides*, *Fries*, we shall soon find that this plant has got a distinct trama, then why a *Paxillus*? It must belong to *Hygrophorus*, and it would be found under *Hygrophorus* if it had white instead of yellowish or brownish seeds or spores. Fungologists say every *Hygrophorus* must have white spores—why? Fries once thought that the spores in *Paxillus* might be either white or brown; then why not in the neighbouring *Hygrophorus*? The answer simply is, there are really no generic or specific bounds to any of these things; they branch and have affinities in every direction; there are no hard outlines by which they can be compassed.

A strong generic character is undoubtedly found in the curious shape of the spores in *Boletus*; they are usually (uniform, as in *B. parvius*, Bull (f, fig. 66), or lanceolate, or ovato-acuminate, whereas in *Paxillus* the spores are almost round: herein then, there surely is a difference. But in *Boletus bovinus*, Linn. (g, fig. 66), the spores are oval, and in *B. rubinus*, W. Sm. (h, fig. 66), they, though really oval, are almost spherical, and indeed, just the same with *Paxillus involutus* itself. It will be seen, from what has now been written, that every character that separates *Agaricus* from *Paxillus* and *Paxillus* from *Boletus* is liable to break down.

After these notes were written, and long after the illustrative drawings were made, we wrote to a correspondent from whom we remembered having received specimens as *Boletus* many years ago, and to whom we at the time replied that his plant was no *Boletus* at all, but one of the *Agaricini*, viz., *Paxillus involutus*. Mr. J. Aubrey Clark, of Street, Somerset, is this correspondent—a keen observer, and a gentleman who has added many new fungi to our flora. His reply to us is curious, and shows how strongly he believed the plant to be a *Boletus*. He says: "I don't myself believe it to be *P. involutus*, but of course I may be mistaken—Mr. Cooke suggested it might be a variety of *B. bovinus*. Mr. Berkeley thought it might be the *Boletus* form of *Paxillus involutus*." Mr. Clarke placed it under a "round-spored variety of *Boletus bovinus*, B. seaber," as he marked his drawings "according to his own, perhaps erroneous, judgment."

Writers like Mr. Charles Darwin have long taught us that there is really no permanence in species, and if there are no definite boundaries to species there cannot be to families. Young botanists are always squabbling about What is an alga?—what a fungus? what a lichen?—is *Saprolegnia* a fungus or an alga? They never seem to think that quite possibly *Saprolegnia* is neither one nor the other—that it may have the characters of a fungus at one time and of an Alga at another. Such is indeed the fact. It may occupy a perfectly distinct place between fungi and algae, and may not belong to either. Then they say, Is it a parasite or a saprophyte?—does it grow on living things or on dead ones? They never dream that an organism may be capable of growing upon both living and dead, and of being a parasite and a saprophyte at the same time or at different times. Indeed, if one ventures to express an opinion of this nature to some young men of the present day one gets looked upon (by them) as little better than a lunatic. The beginners, although they are now fast enough in discarding fixed limitations to species, they stick like grim death to them when they apply to habits of plants or animals or to their own fancies. *W. G. Smith.*

Orchid Notes and Cleanings.

LYCASTE FLAVESCENS.—Visitors to metropolitan shows are apt to be critical, and some are apt to despise whatever does not strike their fancy. Only the other day we saw a well known connoisseur pass with a shrug of profound contempt the very elegant drooping spikes of a *Pendrochium*, merely because it did not suit his taste. A wider knowledge, even if less deep and special, would have prevented such an outburst of questionable taste. A similar narrowness—the narrowness of a specialist—prevented some from admiring the magnificent plant of *Lycaste flavescens*, (fig. 67), when exhibited lately by Mr. Bowring. The colour of the flowers is, indeed, dull, and they are overshadowed by the overarching leaves; but see what a sheaf of blooms there are—255 all told; see how noble the foliage—and the plant itself 5 feet across. It is only professional beauties who like to be always *en evidence*, more modest beauty

the lovely *Epidendrum bicornatum* should see the condition the stock is in here. The big fat bulbs which the plants make are an evidence of rude health; in a number that are blooming one has three strong spikes. *Vanda Parishii* is coming into flower. The true *Lelia furfuracea*, often mistaken for *L. autumnalis*, is doing finely, as also *L. cinnabarina*. *Plumina fragrans* grows like a weed, almost every spike bearing three to four flowers. The greatest rarity of all is a couple of plants of the true *Masdevalla Schimii*, only four of which we understand survived out of an importation of 6000. It is described as bearing six to eight flowers on a spike, in form and colour like the Humming-bird *Masdevalla*, *M. trochilus*.

DENDROBIUM NOBILE VAR. NOBILIUS.—With reference to the notice of this new *Dendrobium* at p. 366, allow me to state a few additional facts as to its history, which Sir Trevor Lawrence does not seem to have quite remembered. The plant was bought by me at Stevens' Rooms, in a bundle of twelve, which cost 12s., and it is rather remarkable that two grand things turned up together—the fine variety of *Dendrobium Brymerianum* exhibited on March 14 at South

hills as the localities; but he says the diameter of the expanded flower is only 3½ inches. The figure in the *Gardeners' Chronicle* indeed represents a flower 4 inches in diameter, but I never saw one smaller in Burmah, though many larger—5 inches is by no means an unusual size. Call it "a variety" or not, the simple fact is, that the plant grows more freely and luxuriantly in Burmah than elsewhere, for all the *D. formosum* there found is of the larger size. Large basket-loads are being continually brought into the town of Moulmein for sale, as it is a great favourite with the Burmese, both for house decoration and for offering at their pagodas. They call it *gayway-ban*, or "silver flower." C. P.

NOTES FROM BELGIUM.—In one of your numbers we read that *Cymbidium eburneum* thrives well under cool treatment. We know that this plant is rather difficult to flower, and after some experience, we think that the cool end of the East Indian-house is still too warm for it. We have a very nice plant of this species, of which we hoped much, but unfortunately the bud did not develop into flower. We did not know that this plant could be grown in a cold temperature, until Mr. Norman told us through your number

FIG. 67.—LYCASTE FLAVESCENS: FLOWERS PALE BUFF.

charms the more by contrast and retirement. In any case, Mr. Bowring's plant was a wonderful specimen, and as such we are glad to give its portrait.

ORCHIDS AT THE PINE-APPLE NURSERY.—Amongst the large and varied collection of Orchids grown at this nursery, there was recently a plant very rarely seen in bloom—*Eulophia scripta*, bearing a panicle of over 100 flowers; the plant has stout cylindrical fleshy pseudobulbs, 9 or 10 inches long, almost as thick as those of a small *Cyrtopodium*, but much shorter. The individual flowers in shape and size are not unlike those of *Oncidium sarcodeis*; the ground colour is pale yellow with a faint olive-green tinge, heavily spotted and blotched with brown. There is here also a quantity of the new Madagascar *Phaius Humboldtii*, with *P. Henryi*, and *P. tuberculatus*; these are growing well. Another rarity which Mr. O'Brien has managed to save out of an importation, almost the whole of which we believe perished, is *Grammatophyllum Rempelianum*; this is from Madagascar, and said to be almost an aquatic. *Lasia acuminata peduncularis* is in quantity in fine healthy condition. *Cattleya Elderado* and *C. Wallisii* are in excellent order. Those, and they are not a few, who have found a difficulty in managing

Kensington from the collection of J. Southgate, Esq., of Streatham, being included in the same. The little plant of *Dendrobium nobile var. nobilius* produced two flowers, the first year on the imported growths, and they were exhibited at South Kensington. It was sold to Messrs. Rollisson on February 13, 1877, for five guineas. It was then grown on, and flowered just in time to be taken to the International Exhibition at Ghent as *Dendrobium Rollissoni*, where it was killed at the base. Then when the sale took place I bought back the plant for £3 5s., and succeeded in raising six plants from the old pseudobulbs, five of which have been distributed. *H. James, Castle Nursery, Lower Norwood.*

DENDROBIUM FORMOSUM.—My attention has been drawn to a figure of *Dendrobium formosum* in *Gard. Chron.*, p. 360, and the appended remarks. If the figure be intended, as I presume it is, to represent the full size of what gardeners call "the large variety," it certainly does not do the flower justice. It is, in fact, rather a small specimen than otherwise. The Eastern Himalayas, too, are given as its home; I would claim Burmah rather for its habitat. *D. formosum* appears to have been first discovered in the East Himalayas, as Roxburgh gives Silhet and the Garrow

of February 11 last; we have since placed our plants in the Odontoglossum-house, and hope we shall succeed in flowering them. We have often read in your columns that amateurs of great renown thought much about *Odontoglossum Alexandræ* having two spikes, with twelve to fourteen blooms on each spike; we noticed that when speaking of such plants they meant specimen plants, which had been for years under cultivation. [Oh dear, no. Etc.] We have much pleasure in telling you that a great many plants of our *Odontoglossum Alexandræ*, which are grown in an ordinary greenhouse, with a temperature of 38° to 42° are, or have been flowering with two spikes, with ten, twelve, and fourteen blooms on each spike. All our Alexandræ are only plants which were imported in May, 1880, and they had then only two or three small bulbs. We have always cultivated them very cool, and we think that our very cool treatment has much to do with the result. *E. Vercaut & Co.*

THE ORCHID-HOUSES AT CLEVELANDS, SOUTHPORT, the residence of R. P. Percival, Esq., are at the present time most interesting to any one who has an interest in this class of plants. A few days ago I had an opportunity of inspecting the plants, and found

that a great many additions have been made since I saw the plants just two years ago; then Orchids were certainly coming to the fore, but many other decorative plants were grown likewise. Now, however, Orchids are in the ascendant. I shall not attempt to go through each house and describe its occupants, but shall just notice a few of the special plants as they came under my notice. For a more complete description of this establishment, I would refer to your vol. xv., No. 389. Entering the large Cattleya-house there described, a grand display of Cattleya Triane in bloom meets the eye. I must confess I never saw such a large number of varieties, and such a quantity of bloom; every conceivable shade of colour that has hitherto been found in this species is here represented. Scores and scores of dark forms where rose-coloured sepals and petals are associated with a deep rosy-purple lip and orange-coloured throat. In some specimens, the colours of the labellum are clearly and sharply defined, in others the purple and orange so gradually cease in one case and commence in the other, that a quite distinct and different variety is produced by the quiet blending of the colours. In other forms the pure white sepals and petals, with slightly pink labellum reminding one of *C. Warscewiczii* deliata, are to be met with. Arranged as those plants are with, I think, only one plant of *Cymbidium eburneum* in flower amongst them, an effect is produced not often matched. Numerous other Cattleyas and Lælias are here in the best of health; large masses of *L. purpurata*, with from eight to twelve leads; *L. elegans*, in quantity and of large size; *C. Warscewiczii*, with six to eight flowering shoots; these latter are very strong and showing flower-sheaths very freely. *L. anceps* is also represented by scores of masses, some a yard across; some were in flower, and had produced four flowers on a spike. Here, too, I saw a remarkable plant of *C. Skinneri*, such a one as, I should say, cannot be matched anywhere. It was in a pot about a yard across, and had thirty flowering-balls, many of these last growths being finer than any on the plant. Of *C. labiata Percivaliana* it is almost needless to say there were some grand specimens, whilst the distinct *C. Sanderiana* with its stout bulb and thick leathery leaves, was rooting and breaking very strong. Besides the large number in pots growing or flowering as described, there were over a hundred large pieces of many of the species described that have been imported this spring and are hanging round the stages until they commence rooting and breaking. *D. crassimida* was here in flower in capital form; so, too, was a fine variety of the old *D. repidatum*. Amongst a lot of imported *D. Wardianum* was one flowering with blooms 4½ inches across. *D. chrysotoxum* was a grand plant nearly a yard through. Grand, however, as are the Cattleyas and Lælias—and numerous too, without—they are followed closely by the *Odontoglossums*. The *O. vexillarium* are a sight worth travelling miles to see; over a hundred plants, the greater part large plants with six or eight or more leading growths, with foliage perfectly clean, each leaf erect, with that slight purple tinge upon them so indicative of noble health: when these are in flower they will be a display worth seeing. The *O. Alexandre*, *O. Pescatorei*, *O. Hallii*, *O. cirrosium*, too, are here by hundreds in the best of health, and flowering very freely and strong; some splendid varieties of each are now in bloom, as well as some fine hybrid forms in the way of *O. mutus*, *O. heliconium*, *O. Andersonianum*, &c.: in these latter forms this collection is particularly rich. A fine lot of *Odontoglossum Rossi* majus in baskets were full of flower; among these were several unusually dark varieties. *Oncidium macranthum* was here doing well, showing flower-spikes of great length. There are many others that might be mentioned, all growing freely, many showing spikes; these, however, will give some idea of the fine collection now being got together at this place. Mr. F. Bellows, who has charge of the whole in managing them well, and deserves much credit for the excellent condition in which everything is kept. The worthy proprietor, too, will gradually have presented to his view such a feast of chaste floral beauties that few even of those who have made this class of plants their special study will ever have had the opportunity of beholding. *W. Swan, Falmouth.*

Notices of Books.

The Gardeners' Dictionary, &c., edited by G. W. Johnson; with a Revised Supplement, including all the New Plants and Varieties to the End of the Year 1880, by N. E. Brown, of the Royal Herbarium, Genl. Bell & Sons. 1882.

The utility of this well-known book has been materially enhanced by the copious supplement prepared by Mr. Brown. The body of the work is, we presume, a mere stereotyped reprint; at any rate, on referring to some of the articles we found them wholly out of date, as, for instance, the article *Pea*, where most of the varieties mentioned have long been superseded by others. The supplement, so far as we see, does not include the newer varieties of cultivated fruits and vegetables, and is in so far defective—a deficiency which is an unfortunate thing for the gardeners who purchase the book, for neither in the body of the work nor in the supplement will they find recent information of this character. What they will find in the supplement is the fullest and best list of recently introduced plants that we know of. It has evidently been compiled, not by a mere haphazard consultation of catalogues and garden lists, but with knowledge and judgment; the consequence of which is that the very numerous duplicate references, unnecessary synonyms, and errors of commission and omission that deface some similar productions have to a large extent been avoided. The very first article, *Abies*, shows how Mr. Brown has endeavoured to bring his part of the work into conformity with the latest and most authentic information. Other instances occur in the articles on plant diseases, such as clubbing in Cabbages, the diseases of Potatoes, Gladioli, and Auriculas, the *Phylloxera*, the Cucumber disease, in which the compiler has managed to give the substance of the most recent information in small compass. In reference to the Cucumber disease, however, we have not found any mention made under that or any other heading of the diseases of other plants caused by nematoid worms of the same general character as that which induces the disease in Cucumbers.

It is to be hoped that this valuable supplement is not stereotyped, so that it may be revised and extended from time to time as may be required. In this hope we point out a few oversights that have attracted our attention in turning over the pages, by no means with a view to unfavourable criticism, but simply for the purpose above stated. *Arbutus* should be *Arbutus*. *Aristolochia Duchartrei* is truly the same plant as *A. Ruiziana*, but the latter should be the adopted name, the former the synonym. The *Kelepinoras* of gardens are referred to *Chamecypris*, but it is pretty certain that they are only forms of *Thuya*. *Davidsonia pruriens* is no mere garden name for an undetermined plant, but one applied by Baron von Mæler to a remarkable and rare name *Saxifragaceae* plant (see *Gardener's Chronicle*, vol. vi., p. 510), introduced by Mr. Bull. *Vetchia japonica* is well known to have been founded on a shoot of a Spruce deformed by an insect in the same way as our common Spruce Fir so often is, and should have been deleted. All that we need say further is to wish that as much care could have been expended on the revision of the body of the work as has been devoted to the supplement.

Cassell's Concise Cyclopedia.

A good cyclopedia is indispensable, and certainly no garden library should be without one. Messrs. Cassell are now bringing out one which has the merit of cheapness. It is too early to pronounce definitely on its merits, but if we are to take the few botanical articles in the part before us as samples we may venture to suggest to the compiler that in a cyclopedia, even a concise one, accuracy and utility are the main things to be aimed at. The article *Aconite* is vague, not technically accurate, contains some things that are nearly useless to the ordinary reader, while matters of much greater importance are omitted. So in the case of *Allspice*; some information is given, but no mention whatever is made of the part of the plant which furnishes the spice. Under *Alge* not a word is said as to their reproductive organs. The article devoted to the Alder is similarly meagre.

—The *Scientific Kall* (Bradbury, Agnew, & Co.).

—The last issued part contains the continuation of the essay on the relation between solar phenomena and climatic cycles, by Prof. Archibald. A very useful index is given with the present part. The importance of systematised notes, with an index like that now given, must render this publication very valuable to busy workers. At present only matters relating to climate are dealt with.

The Kitchen Garden.

ASPARAGUS PLANTING.—Notwithstanding all that has been written for our information by those conversant with the French system of growing Asparagus, the home productions cannot yet be said to have attained the standard of excellence which distinguishes the French "grass." The French growers, as is well known to most of our readers, allow a greater area for the development of the individual plants than has hitherto been given them by English growers; and this may have been an important agent in the production of the splendid examples of Asparagus which are sent to London in the season by the growers from the neighbourhood of Paris. And with this object in view we shall at once proceed with the French *modus operandi* of planting the roots. The ground having been trenched as previously recommended, open trenches 4 feet from centre to centre, 9 inches deep, and 15 inches wide, in the centre of which make little hillocks a couple of inches high and 3 feet apart, on which lay the roots of the plants, spreading them out equally in every direction, and then cover them with a few inches of fine soil, and subsequently with a little well-decomposed manure, which will tend to preserve the roots in an equable condition, and afterwards water through a rose to settle the soil about the roots. For this purpose we prefer one-year-old plants, which we plant as soon as the young shoots appear through the soil in the nursery beds, pressing the soil moderately firm around the roots with the hands at the time of planting. After which a small stick should be put to each plant, to which to tie it for support later on. In addition to the trenches we still plant in beds, but in a modified form, for instead of planting three longitudinal lines in each 4-foot bed we plant two only. The beds, as already stated, are 4 feet wide, with alleys 2 feet wide between them, and are marked out for two rows of plants in each bed at 9 inches on either side the centre; drills are then drawn about 3 inches deep, and in these the roots—taking half of them in one hand and half in the other—are placed, with the crowns in an elevated position 18 inches apart in the row, and the soil pressed about the roots with the hands; the plants are then staked, and the surface mulched, as recommended above. To supply plants for forcing the fourth year after planting we plant in drills, as above recommended, 15 inches asunder, and the same distance from plant to plant in the row, and in such a way that the plants in the second row stand angle-wise to those in the first—this remark also applies to those in beds, these being planted in consecutive drills—and so on with each succeeding row, which gives the individual plants more room to develop themselves than if planted opposite. In the meantime rows of Cauliflower, Cabbage, or Broccoli can be planted between the Asparagus trenches, which are 4 feet asunder, without in any way interfering with the growth of the latter.

PEE-SLEED SOWING, &c.—Sow the main crop of Beet (*Prime-Appl* Short-top, when obtained true to name, is the best variety) in good open soil, in drills 15 inches apart. A sowing of Osborn's Early Forcing and Canadian Wonder French Beans should now be made out-of-doors in a warm border, where provision can be made for protecting them from late frosts when the plants appear through the soil. Slugs and grubs are not unrequently very troublesome and destructive to freshly planted Cauliflower, Cabbage, and Lettuce plants; the latter should therefore be looked over every morning with a view to destroying these depredators, and tilling up the blanks which they may have made, until the plants have established themselves, when they will be better able to resist the attacks of these pests. When the roots and stems of plants have been eaten away by the grub the drooping leaves indicate the fact, and the former, as above stated, should then be hunted for and destroyed before making good the blanks. If young Lettuce plants, together with seedling Turnips, Cabbages, &c., just as they are appearing through the surface of the beds and drills are dusted over when the leaves are damp with a mixture of lime and new dry soil, it will not only effectually check the ravages of slugs, birds, and flies, but—the application being persisted with when necessary—will entirely prevent their being

ALTERNANTHERA PARONYCHOIDES AUREA.—This should be noted as a most desirable carpet-bedding plant for summer work. The leaves take a fine yellow hue, unlike any we have in any other bedding plant. It also appears to colour well when in the sun or in the shade, or whether the weather be dull or gloomy. All the *Alternantheras* do best in an open sunny position, with a free rich soil at their roots and an abundance of water.

interfered with by the latter. Carrots and Turnips will require being thinned out to a couple of inches in the rows, to be finally thinned out a few weeks later, which, in case of mishap to the plants when young, will be the safer mode of procedure. And ply the Dutch hoe freely between the rows, as also between those of Onions, which have with us come up nicely.

GLOBE ARTICHOKE.—Now that the plants have made sufficient growth to admit of offsets being taken off to make good any deaths that may have taken place during the winter, and also for the purpose of making fresh plantations, our plan—and doubtless that of many others—is to destroy a few rows of the oldest plants every year, at the same time saving therefrom enough of young plants wherewith to plant an equal number of rows, which are planted in clumps of three plants set triangularly, in rows 4 feet asunder, and at the same distance from clump to clump, in rich well-prepared ground. When planting the soil should be made firm around each plant with the hands, after which they should be watered, to settle the soil about the roots, and the ground between them should be subsequently mulched with a few inches thick of well-rotted manure. These plants will yield a good supply of Artichokes late in the autumn, and long after those which have been planted a year or two previously have ceased to bear. The manure that was put on as a surface-dressing and protection to the roots of the plants late in the preceding autumn should now be forked in, the blanks, if any, having been previously filled up.

THE HERR BORDER.—If not seen to, as recommended in a previous Calendar, no time should now be lost in doing so, as in many establishments the demands for its produce are large and frequent. Therefore, in order to maintain a young and plentiful supply, it will be necessary to make fresh plantations of the respective kinds, amongst which the following varieties will be most sought after—viz., Tarragon, Mint, common and Lemon Thyme, Sage, &c. These are readily increased by division of the roots and slips, and which should be planted in rows at from 10 to 15 inches asunder. And this, like all other departmental work, should be performed neatly.

FORCING DEPARTMENT.—Seeds of February Tomato which were sown the last week in February for planting out-of-doors in May should now be potted off singly into large 60's, and another pinch of seed sown to raise plants for the main crop. Another batch of French Beans should also be sown in pots, to be transferred to pits later on, and see that those at present in vinerias and Peach-houses are kept free from red-spider by giving them plenty of water at the roots, and syringing the plants a couple of times a-day overhead.

PITS AND FRAMES.—See that Celery plants, together with Brussels Sprouts, Cauliflower, Cabbage, and Lettuce plants, as they increase in growth, have the lights taken off on warm days, and tilted up at night, preparatory to being planted out shortly, and that they have sufficient water at the roots. *H. W. Ward, Longford Castle, Wilt.*

Peaches and Nectarines.

WHERE roots and borders are all right, with plenty of good drainage, Peach trees in early houses will be making rapid growth. The fruit may now be finally thinned, as all that are inclined to drop during stoning will have done so before this. Leave the finest and best placed fruit from 9 to 12 inches apart all over the tree, if possible. Pay close attention to watering at the roots, and to syringing the trees well with tepid water. Succession-houses will require constant attention as regards disbanding and tying down. They also may now have a good mulching of rotten manure, and afterwards a thorough soaking of tepid water.

Late houses will now be in full bloom—at least ours are, and very full indeed they are; but I have had them well thinned, pulling off all the blooms on the underside of shoots, and reducing doublers and trebles down to one, leaving the strongest and best placed bloom, which fertilise according to directions already given, and keep the houses as cool as possible. *J. Wallis, Keele Gardens.*

Plants and their Culture.

STOVE CLIMBERS.—These will now be growing away freely, give them therefore every encouragement, regulate the young growths, and watch closely against the inroads of insects. These kinds of stove plants, especially of the flowering section, are always valuable for cut purposes. A great deterrent to their more extensive cultivation is, no doubt, to be found in the harbour which they afford to insects, thereby causing many a fine plant to become unpopular from unfair causes. Of these plants the Stephanotis is an accepted favourite, plants that were treated (as advised in last season's Calendar) to a good thinning-out of the weaker wood, and securing a good autumnal growth, will now be either in flower or very nearly so, under the ordinary treatment of the stove. For some weeks to come these will prove useful, and be succeeded by Passion-flowers, Clerodendrons, and Dipladenias, &c., during the summer. Climbers will generally succeed best if they can be turned out of pots into a bed of soil; Dipladenias, however, should be kept in pots, and Alamandias also, otherwise the latter will grow too luxuriantly. *Hoya impenalis* is a grand stove climbing plant; it is some years since I saw this in good condition. We intend to place it on the roof here as soon as our plant is large enough. Where room can be afforded the *Aristolochias* will be found interesting as well as curious, but beware of their enemy, the red-spider.

BEGONIAS.—Of these the shrubby and evergreen varieties, generally classed as stove plants, will be found to do better in an intermediate-house. From now onwards for some months *B. nitida* and its white variety, *B. n. odorata*, also *B. aesculens*, will all give a good display. Two other good flowering kinds are *B. metallica* and *incarnata purpurascens*, both of which have also handsome foliage. We grow *B. nitida odorata* somewhat extensively; though of straggling habit it is very useful for grouping in the summer among other plants in the conservatory, lasting a long time in flower under these conditions. The ornamental foliaged kinds will now be pushing up new growth; any that have become overcrowded in the pots they are now occupying should be divided. I find a few pots of these are very handy in the conservatory during September and October. The tuberous rooted kinds will now in most cases show signs of activity; finish potting these if not yet completed. For want of better accommodation we grow ours in a Peach-house. They succeed there very satisfactorily, the liberal ventilation and cool night temperature suits them, neither do they seem to mind the wetting they receive from the trees being syringed, the only drawback being that we cannot keep them so close to the glass as we would like to do. Seedlings of these from seed sown this spring should be pricked off into pans when they are large enough to handle.

GREENHOUSE AND PITS.—Some of the *Acacias* and *Cytisus* will now be in flower, and others fast advancing towards that stage. Keep them well supplied with water; if allowed to suffer long now, they will fade much sooner. These and *Chorozemas* in flower will be prolonged in the flowering stage if a slight shading can be given during very bright sunshine. *Tetrathecas* (*Tremandra*) *cricifolia* and *verticillata*, I think, always look best when the sun is shining upon them, so also do the *Aphelaxis* and *Phenocomas*. Both of these latter class of plants must not on any account be wet overhead when expanding their blossoms, or they will soon turn mouldy. Young stock of *Pteronia elegans* should be kept pinched frequently to get a well-furnished bottom. If any of these are becoming pot-bound a shift would be beneficial, using good fibrous peat and silver-sand; if the peat is not exactly what can be desired, add some small pieces of charcoal, or the same of broken crocks—this will help to keep the soil open. Some cuttings put in now of the *Statice*s will be found to strike freely. *S. profusa* is one of the best, and ought to be grown in quantity. Plants of *Agaves*, *Bonaparticas*, *Dasylirions*, and

Yuccas, that have been kept on the dry side during the winter months, should now have a good soaking of water; after which, any that may require potting should be seen to before the roots become too active. These will all succeed well in a soil consisting of about equal parts of sound turfy loam and fibrous peat with all the finer particles extracted. Add to this a good proportion of silver-sand, and also some charcoal if at hand. Take pains in potting these plants, working the soil firmly around the old ball. *Liliums*, as *auratum*, *longiflorum* (unless wanted for early bloom), and the varieties of *speciosum* will do well in cold pits. Imported bulbs of the first-named are with me just pushing their young growths above the soil. *James Hudson, Gunnersbury House, Acton.*

The Drangery.

If the fruit is well set and swelling, and the trees clean as well as in good condition, the cultural requirements henceforward will be very simple. The night temperature should be about 60° to 65°. If the trees are plunged in pots they will not require nearly so much water as those exposed all round to the atmospheric conditions of the house. If the house is shut up close all night a little air ought to be admitted at the highest part when the trees are syringed in the morning, and as the temperature increases by sun-heat add more air. If the temperature by sun-heat reaches 80° it will be high enough. The water applied either to the roots or leaves of the trees ought to be warmed by standing over the hot-water pipes. It is a good arrangement in moderate-sized houses of any kind that are used for forcing to have a small galvanised iron tank, to hold from 20 to 40 gallons of water, placed over the hot-water pipes; and whenever any water is taken out of it replace it at once, so that there will always be plenty of tepid water when it is needed. Frequent syringing of the trees is conducive to healthy development, and occasional watering with weak liquid manure is desirable when the soil in the pots is exhausted. If there is any black fungus on the leaves it ought to be washed off with a sponge and warm soapy water. Scale must also be removed by hand washings; and if by any chance mealy-bug has got on to the trees this must be removed in the same way. If anything like success has to be attained it can only be by keeping the trees clean. In other respects no fruit is easier grown. *J. Douglas.*

Apiary.

THE WILLOW FOR BEES.—I am not now going to write about the white Willow (*Salix alba*), nor the Bedford Willow (*Salix Russelliana*), nor yet of the crack Willow (*Salix fragilis*), any one of which, planted in a suitable situation in quantity, will purchase a horse, while most other trees will only buy his saddle—nor am I going into a long account of the black, green, and golden Osier, all of which we have woven into useful baskets when the weather rendered outdoor work impracticable; but I write to call attention to the Goat Willow (*Salix caprea*), which was known and planted as early food for bees 2000 years ago. Virgil says—

“The Willow hedge which parts your neighbour's land
To bees of Hybla yields untiring store
Of sweetest nectar, and with constant hum
Invites repose.”

And yet, strange to say, few persons are now aware that the catkin of this Willow is the very first food which our honey-bee gets. Some ten or twelve years ago I had a capital opportunity to plant several hundred yards of this Willow simply as early food for the bees in the garden; the situation was somewhat damp, and they have now grown 15 and 20 feet high. The blossom this fine season has been remarkably marvellous, and all day long and every day during the month of March the trees have been literally swarming with bees, and at the hives as busily carrying in their stores as if it were flowery May or leafy June. There is no need to speak of the value of bees in field and garden, they unquestionably help to fertilise our fruit trees, and indeed I look upon them as part and parcel of the garden. Willows of all kinds are of all things the easiest to grow, and no water-courses, stream, river, or lake is perfect without the Willow being associated with it, and it is this tree which yielded the Palm used by our forefathers at this season of the year. *J. Kest, Zetrig Castle.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	April 3	Sale of Imported Orchids, at Stevens' Rooms. Floral Exhibition, in the Town Hall, Main Chamber.
TUESDAY,	April 4	Sale of Established Orchids, &c., on the Garden Nursery, Newmarket, by J. Horthcote & Morris. Spring Show at Newcastle upon Tyne.
WEDNESDAY,	April 5	Sale of First Portion of the Life Mr. Russell's Orchids, at Stevens' Rooms. Meeting of the Linnean Society, at 8 P.M.
THURSDAY,	April 6	Sale of Imported Orchids, at Stevens' Rooms.

NO stranger who visited the rooms of the ROYAL HORTICULTURAL SOCIETY on Tuesday last could have imagined that the old Society was suffering from the shocks of adverse fate. True, the arcades presented their customary appearance of dust and dilapidation, and were possibly a trifle worse than usual from the well-meant, but, in this case, not successful, attempt of the Smoke Exhibition authorities to cleanse the air of the locality. Whatever may be the ultimate outcome of the efforts of the anti-smoke agitators, it cannot be said that they have improved the arcades, while their experiments in the great conservatory have been such that the anti-vice-insectors, were they not just at present too much pre-occupied with the fate of a mouse or two, might be called on to remonstrate over the injuries and loss inflicted on noble Tree Ferns and secular Cycads. But arcades and conservatory, Cycads and Ferns, we presume, are no longer to be considered as the property either of the Society or the debenture-holders. Money was borrowed to be expended on the buildings, which are handed over, not in part, but wholly, to the landlords, who will, in the face of their recent legal victory, probably laugh at any claim, on the part of their tenants, for unexhausted improvements. Some understanding will, however, it is to be hoped, be made between the two bodies—the Society on the one hand and the Commissioners on the other—as to the future of the Society. Overtures to this effect are we believe being made, and it was announced on Tuesday last that a circular explanatory of the present state of affairs will shortly be sent to every Fellow. We are quite unable to forecast the probable action of the Council, but we may with confidence bespeak on their behalf the earnest support of all who are interested in horticulture. We do this from the knowledge that the Council never contained so large an infusion of *bonâ fide* horticulturists as at present, men devoted to its pursuit and earnest in their endeavours to promote its welfare and that of the Society of which they are the administrators. The way in which Chiswick has been maintained throughout these troublous times, and the manner in which the committees have been kept together are sufficient to show that the Council have done their best under difficult circumstances, and this is further shown by the manner in which month after month throughout all these years the exhibitors have rallied round them. It is difficult to suppose that such continued support would have been given by this class of well-wishers, if there were not a well rooted feeling that the vitality of the sorely tried Society was proof against even greater trials than it has yet passed through, and that, taken for all in all, the Council have done their work untiringly and well. Even the general public, who have often been strangely unappreciative of the excellent exhibitions provided for them, seemed on Tuesday last to have waked up to the fact so well known to horticulturists that the exhibitions are worthy their inspection, for, on the day in question, they mustered in such considerable numbers that circulation in the conservatory was not an easy matter. What with the extensive and attractive display alluded to in another column, and what with the number of persons present, it was, as we have said, difficult to appreciate the fact that the old Society was

passing through perhaps the most intense of its many crises, one feature of which is entirely in its favour—we mean the extinction of the debenture debt.

The Commissioners hold public money in trust for the benefit of the people, especially in matters of education, science, art, and culture. It may well be considered, therefore, part of their duty to encourage horticulture, which does so much to enhance the physical welfare and increase the refinements and enjoyments of life. It is to be hoped that they will see the matter in this light. It may add to their resources to build a new street in their property, but in the public interest it is much more important to keep an open space, not only for health-sake, but for the protection of the Natural History Museum, the Albert Hall, the South Kensington Museum, and their priceless contents. It is clear that the interests of the public are bound up with those of the Royal Horticultural Society, and this fact will, it is to be hoped, be duly weighed by the Commissioners.

— CRAGSIDE.—In our number for September 11, 1880, we gave a description of the finely situate residence of Sir W. ARMSTRONG; that we were not unduly laudatory the illustration (fig. 68) we now give may serve to show. We need not recapitulate what has been already said as to the reclaiming of the moorland, the plantations of Scots Pines, the gardens, the rockeries, the ferneries, the collection of alpine plants and other matters for which Cragside is famous. To some extent and in varying degrees these features may be seen elsewhere, but it is only natural to expect that here mechanical genius shall show itself in such matters as hydraulic rams, and that falling water shall be made the source of light—water at one end brilliant light at the other, in between the two the mechanical force of the descent of the water, a whirling of giant magnets one over the other—a stirring up of force, led by a ductile wire to a series of fairy lamps throughout the house. We should be glad to hear that Sir WILLIAM, who is a lover of his garden, was following the example of Dr. SIEMENS and instituting further experiments on the potency of the electric light in the culture of plants.

— THE SHOW AT THE ROYAL HORTICULTURAL SOCIETY on Tuesday was unusually interesting. The truly wonderful *Coryanthes* shown by Sir TREVOR LAWRENCE, with its large yellow flower-segments, in shape like elephant's ears, and its extraordinary bucket-shaped, purplish lip overhanging by two horns where nectar is distilled into the cavity of the bucket, and the marvellous adaptation of its singular mechanism to the purposes of insect fertilisation is more curious and interesting than the elephantine Jumbo, and should elicit an equal amount of enthusiasm—that is, if enthusiasm meant the something as knowledge and appreciation. Of other Orchids there were some splendid varieties exhibited, but, though rich in colour, not presenting the same interest as the *Coryanthes*. Again there was sent from Kew a leaf and a portion of the inflorescence of the stately *Doryanthes Palmeri* figured in our last number, and a climbing plant from Borneo, sent by Messrs. VEITCH, and fine enough in the bronzy colour of its pinnate foliage and its silver-striped leaflets to be mentioned in the same breath with *Cissus discolor*, to which Lee is allied, but to which, however, it is scarcely equal. Mr. MANGLES' splendid *Rhododendrons* compelled the admiration of all who saw them, while the facts elicited in the course of his descriptive account of them at the Scientific Committee are of great interest to hybridisers and present problems for solution. Why, for instance, is a cross between two species possible when the pollen of one species of *Rhododendron* is dusted on to the stigma of another when the reverse cross between the same two species is impossible? The different appearance of the Malayan and the Himalayan species of *Rhododendron* affords a reason for their mutual sterility—a sterility, however, not due to differences of locality, seeing that the Chinese *R. Fortunei* crosses with the Himalayan Thomson. The Society is doing a more important and valuable duty by eliciting such observations as these, made by a careful and reliable experimenter, especially when backed up by the exhibition of such noble results, than by awarding First-class Certificates to plants of minor interest, which are the fashion of the hour—here to day and

superseded to-morrow, because they have nothing but superficial prettiness to recommend them.

— LINNEAN SOCIETY.—The President of the Society, Sir JOHN LUBBOCK, Bart., M.P., held a reception on Thursday evening last in the rooms of the Society at Burlington House. This is the first occasion in which a similar gathering has been got together since the Society entered upon its new quarters some years ago. The success of the *soirée* will, we hope, prove satisfactory to the President and Council, as indicative of the goodwill of the Fellows and their appreciation of the opportunity of paying respect to the President and of meeting together in familiar intercourse. The *soirée* was largely attended, and the contributions from the Royal Gardens, Kew, Messrs. VEITCH and WILLIAMS and others, attracted much attention. The cut *Rhododendrons* shown by Mr. MANGLES and the Hon. and Rev. J. T. BOSCAWEN also elicited much approbation. Mr. CHARLES WHITE's extensive series of pencil drawings of pollen grains were much appreciated, the prominent defect being that there was apparently no definite scale of comparison as to relative size.

— RHODODENDRON GLAUCUM HYBRIDUM.—Mr. BURKHIDE sends a very pretty variety under this name, sent out by Messrs. METHVEN & SONS, of Edinburgh. It is a dwarf variety with small oblong lanceolate leaves, thinly sprinkled on the under-surface with flat brown scales intermingled with yellow glands, which emit an aromatic fragrance. The flowers are borne in terminal trusses, each borne on a slender rather long stalk and with a short calyx with fine roundish blue leaves, and funnel-shaped corolla of a rosy-lilac hue with a five-lobed spreading unspotted limb, about 1½ inch in diameter. It is a charming variety for the rockery.

— LINNEAN SOCIETY.—The papers to be read on Thursday, April 6, at 8 P.M., are:—1. "On the Connection between Geotropism and Growth;" by FRANCIS DARWIN. 2. "Birds of New Guinea;" by R. BOWLER SHARPE. 3. "Note on a Negative Heliotropism;" by B. DAYDON JACKSON. 4. "Mollusca of the *Challenger Expedition*;" by the Rev. R. BOGGS WATSON.

— MR. J. FORSYTH JOHNSON requests us to state that he has opened a new office at 90, New Bond Street, W., to which place all communications respecting his business as a Landscape Gardener, should now be addressed.

— MAGNOLIA CONSPICUA.—The first specimen of the Chinese white *Magnolia* growing in the grounds of Gunnersbury House, Acton, has this season bloomed with more than its wonted freedom. The whole surface of the branches is literally covered with large pure white fragrant flowers that were unshapely much disfigured by the snow, frost, and cutting winds of the 21st and 22d ult. Notwithstanding that the tree is sheltered somewhat by the dwelling-house, it yet suffered, as might be expected. But it is a beautiful object just now, and, occupying the highest ground, the tree in the dim twilight stands out against the budding yet nude branches of Elm and Chestnut like a huge arboreal ghost. It is a rare characteristic in the tree that it flowers so early; but, alas! this early blooming is often the cause of great disfigurement of beauty.

— THE PARCELS POST.—The announcement made in the House of Commons on Monday evening last, of the intention of the Post Office authorities to establish a parcels post as soon as the co-operation of the railway companies is assured, will be received with satisfaction by the horticultural trade and by amateurs. Judging by what has already been done by both florists and seedsmen in the use of the post-office as a distributor of plants, cuttings, and seeds, we might indeed suppose that a parcels post would come to them as a great boon, for 12 oz. parcels have proved so small as to limit trade largely, whilst the expansion up to 7 lb. means not only seeds enough for a fair-sized garden, but plants of fair size by the dozen. Hitherto plants sent per post have not been quite as good as the purchasers might desire, or perhaps expect. The postal limits were too restricted to permit of good well-rooted stuff being sent; and thus where the recipient was without glass, and specially a little artificial heat, weary indeed was the time that had to elapse before the potted plants were established and presentable. With seeds also the limitation has told

injuriously. Quantities have been too small and kinds limited. Presently larger seeds of various kinds may be included, much to the benefit of both seedman and purchaser. The only serious argument put forth against a parcels post is the one that small shopkeepers in rural districts will suffer because their whilom customers will be able to get better commodities from large towns. That may or may not result, but if the public benefit, and trade generally

Go where one will, it is alike at home. Its bright yellow blossoms are probably not exceeded in brilliancy by any other shrub flowering at the same time of year, unless by *F. suspensa*. The plant which has suggested these observations is growing luxuriantly in an exposed situation in Gloucestershire, having upon one side a good plant, also in flower, of *Berberis Darwinii*, and upon the other a nice specimen of *Ribes sanguinea*. But the *Forsythia* is by far the most striking object in the

a spike, and is a remarkable specimen to be grown in a 9-inch pot. The flowers are creamy white, beautifully scented, and are nearly as large as those of *Magnolia conspicua*. Restriction at the root is the secret of its profuse flowering condition. The plant has been potted once in thirteen years!

— CHARCOAL IN POTTING SOILS.—The value of this article as an agent in keeping potting soils open

FIG. 68.—CRAGSIDE, NORTHUMBERLAND, THE RESIDENCE OF SIR WM. ARMSTRONG. (SEE P. 436.)

is increased, individuals must be content to suffer. What is much more likely to result, however, is that a new impetus will be given to trade in certain articles, of which plants and seeds may not be the least important. New vehicles for carriage means new wants supplied, new demands created and met. Those tradesmen will be the wisest who specially prepare for the newer forms of transit.

— FORSYTHIA VIRIDISSIMA.—Wherever planting is done with a view of having early spring effects, this elegant deciduous shrub should not be omitted.

distance, especially when a sudden flash of sunlight momentarily plays among its golden blossoms, which renders them still more beautiful. The plant in question has grown more freely than usual, and is by no means a formal shaped shrub, which adds still further to its charms as a shrubbery border plant.

— RHODODENDRON NUTALLI.—A very fine example of this variety is now in flower at Cote Hoase, Bristol, the seat of H. ST. VINCENT AMES, Esq. (Mr. BANNISTER, gardener). The plant has eleven flower-spikes with from three to five flowers to

and porous can hardly be too highly estimated; such prime Auricula growers as the Rev. F. D. HORNER, Mr. E. SIMONITE, Mr. S. BARLOW, and others use it largely in their composts, and with the best effects. It is not a mere mechanical agent like sand, but an active principle, having, as LIEBIG remarks, "a physical as well as a chemical effect on soils decidedly useful. It renders them, as far as it is present, light and friable, and gives additional warmth to them by its colour, which absorbs and retains readily the rays of the sun during the day; wherever charcoal has been applied rust never affects the growth of Wheat."

Those who use charcoal in Auricula soils find less losses among their plants than when sand is employed to give it a porous character, and the roots ramify more freely in it. The cost of charcoal as compared with sand is much heavier, but its operation is so beneficial as to compensate in a great degree for its extra cost. Then there is the labour of breaking it up small enough for potting purposes; if it could be hought reduced to finer particles it would be decidedly advantageous, and perhaps this boon will be allowed should the demand for it materially increase.

— MUSAS AS FLOWERING PLANTS.—A variety (unknown) imported from Madeira is now in flower at Cote House, Bristol, under the care of Mr. HANNISTER, who grows it at the cool end of the plant stove. The plant is furnished with long, rather narrow, drooping leaves, and produces a cone-like flower-spike of considerable length, consisting of a series of scarlet bracts tipped with orange, which gives the plant a striking appearance. It will be found a most valuable addition to our stock of furnishing plants.

— WILD FLOWERS.—A writer has been somewhat loudly lamenting in a daily paper the gradual demolition that is going on of wild flowers in their rural haunts, especially through the instrumentality of plant hawkers. That this is too true is painfully evident from the fact that only in the most secluded rural districts can Primroses now be seen growing on the roadside, and only in carefully preserved enclosures can these most charming of our indigenous spring flowers be found at all. The town dweller will buy anything presented in the shape of a flower, but especially delights in those which come fresh from the woodlands and pure country air. Thus Primroses, if they can be found by the industrious depredators, are when in bloom always profitable, and large breadths are cleared with surprising rapidity. The country is in fact becoming denuded of myriads of plants that are its most lovely of floral gems, not to satisfy some real want, but almost exclusively to gratify a natural but none the less an unreasonable sentiment, for these plants do but go by myriads to their death. What is true of Primroses is not less true of many other kinds, and specially of hardy Ferns, upon which the plant collector preys with marked avidity. If the Primrose trade is such a profitable one, it seems strange that growers do not save seed and raise them in vast quantities. Perhaps in a cultivated state and removed from the welcome shelter of trees and hedges, they will not seed freely, and thus their garden cultivation becomes difficult. Perhaps they can yet be obtained too cheaply from native habitats to make garden cultivation of them remunerative, but some day the Legislature, awakening to the fact that our hardy plants are disappearing from the face of the earth, may place them under the protection of the law, as it has done the wild birds, and render their destruction penal. Wild flowers add charms to rural life much as the stars add interest and beauty to the sky. Rural life without flowers in field and wayside would be as unendurable as the entire extinction of the feathered songsters would make it. We want the wild flowers preserved to us and to our posterity. To gather a handful of their pretty forms as the country rambler is taken is indeed a delight, but the wilful destruction of myriads, whether as roots to gratify the sentiment of the town dweller, or as flowers to secure prizes at flower shows, is objectionable and should be repressed.

— CAMELLIA LA CAMPACE.—In the Camellia-house of FRANCIS W. SAVAGE, Esq., Springfield, near Bristol, a well grown plant of the above named, a seedling from Florence, is now producing a fine display of flowers. The plant is in rude health, and as a consequence the leaves are of an oily green and the flowers well developed and of much substance. The flowers present a greater variety of colour than any other known kind; they are carnation-lake on a pale ground veined with bright carmine. The flowers have a distant resemblance to the well known kind, Jubilee, but of greater variety of colour.

— THE QUEEN AT MENTONE.—On Saturday last, March 25, the garden of Mr. THOMAS HANBURY, Islazzo Orengo, La Mortola, Mentone, was honoured by the visit of Queen VICTORIA and the Princess BEATRICE, accompanied by Lady CHURCHILL and the Hon. Miss BAILLIE. The Royal party remained about two hours, and expressed

great admiration of the varied views, HER MAJESTY sketching one of the most striking from Mr. HANBURY'S drawing-room window. The plants in flower more particularly admired were *Pteronia incana*, from Natal, with its delicious scent, like a ripe Peach; *Cantua dependens*, with its splendid clusters of drooping red flowers; the great *Echium*, from Mexico, *E. candicans* having a spike of white flowers over a yard in length; *Banksia marcescens*, with its huge bottle-brush heads; the delicate-tinted *Dryandra floribunda*, from Australia; *Altonia exensis*, with its elegant pink seed-pods; *Aloe Hanburyana*, with its splendid head of coral-like flowers; *Graya Sutherlandii* and *Bignonia venusta*, both flowering here for the first time; *B. caprolata*, *Akebia quinata* and *Stauntonia latifolia*, both from China, and having very sweet-scented flowers; *Bougainvillea Warszewiczii*, with its magenta bracts, now becoming common in gardens along the coast. Some of these flowers, presented by Mr. HANBURY'S children, were graciously accepted by HER MAJESTY. Curiously enough, Mr. HANBURY had just received from his friend Mr. FORREST, H.M. Consul at Amoy, in China, fine specimens of *Cycas revoluta*, which had been seen and admired there by the Royal Princes before being shipped off. The extreme mildness of the season also enabled Mr. HANBURY to present to HER MAJESTY a dish of the ripe fruit of the Loquat, *Eriobotrya japonica*.

— AUBRIETIA PURPUREA AND ARAIS ALBIDA.—These two spring flowering border plants, which are familiar almost to every one, are usually effective, and this season they are especially so. The object of these remarks is, however, to point out the cheerful effect which may be created by planting patches of both plants alternately. It is not necessary, nor even desirable, to plant the patches in mathematical order, as long as the two colours are approximating to each other, to produce the desired effect. The idea is practicable alike in the rocky as in the herbaceous border, and of the two situations perhaps the former would give the most pleasing effect.

— DOWNWARD GROWTH OF STEM.—Mr. JENNINGS sends us a bulb of a Hyacinth which has produced one flower-spike in the usual manner, and a second downward into the water of the glass in which it was growing. It would seem that the obstruction offered by the neck of the glass to upward growth of the bud in question made it reverse its usual direction.

— SEMPERVIVUM ARBOREUM VARIEGATUM.—Since carpet bedding has been so extensively carried out in the public parks and many private gardens, the different varieties of *Sempervivum* have taken a prominent place as decorative subjects for particular styles of flower gardening. Heretofore the stock of bedding *Sempervivums*, although beautiful in form and chaste in appearance, lack that attraction which is always centred in a variegated plant over one that is entirely green, however chaste the latter may be in habit or distinct in shape. In the above variety will be found a real gem for bedding out, a plant that will make a charming association with *Alternanthera* and other dwarf foliage plants.

— THE SEASON IN SCOTLAND.—A Midlothian correspondent writes:—"So far we have had an extraordinarily mild winter and spring, and vegetation is far advanced for the season. Appricots are set well, and are now the size of large Peas. Peaches are nearly as forward, and Plums are in full flower. Most sorts of Pears and Cherries will be in full flower in the course of a few days, and Apples are fast following. The earliest Gooseberries are about fit for tart, and even Strawberries are showing their flowers quite prominently. With the exception of Pears on walls, which are very thin of flowers, all kinds of fruits look most promising for a good crop, but it is rather too soon to speak with safety, as a frosty night may yet sweep all away. After such a season as 1881 was in this district we did not expect a crop of fruit this year, because, generally speaking, the wood and buds were not so well ripened as to lead us to expect the flowers to "set" in any numbers, but the fine weather since October has probably helped them, and the fruit is "set" as thick as we can wish it so far. Last week was rather cold, but we had no frost to hurt anything.

— STACHYRUS FRACOX.—Travellers who have seen this plant in its native haunts on the

Japanese hills, or cultivated in Japanese gardens, state that when fully in flower in March it presents a splendid effect, owing to the great abundance with which its racemes of blooms are produced. In colour these are greenish when young, changing to white as they grow older. There is, however, one drawback connected with them, and that is a somewhat disagreeable odour. In the winter garden at Kew there is a plant now in bloom. The species has been successfully grown in the open both at Paris and Angers, so under favourable conditions it would probably do well in many places in this country. The winters of 1870-50 and 1880-81 proved too much for the individuals tried outside at Kew.

— VINES FROM COCHIN CHINA.—It is only the other day that we had occasion to comment on some of the succulent-stemmed Vines of Soudan, recently introduced into France with expectations—doomed, we fear, not to be realised—that they would succeed in that country, and furnish a substitute for the ordinary Vines destroyed by the Phylloxera. Another candidate for trial is now announced from Cochin China. M. Martin, the Director of the Government Garden at Saigon, has sent seeds of a Vine growing in Cochin China to Messrs. Vilmorin, together with a descriptive letter detailing the experiments made in the production of wine. This species, it appears, has tuberous roots, by means of which, as also by seeds, the plant can be propagated. The plant dies down annually, and is easily cultivated on poles or trellises, like Hops. The plant is described as attaining a height of 50 metres and upwards, and to be covered with very large bunches of fruit. The wine is of a green colour, very poor in alcohol—a recommendation to teetotalers—and not very commendable as to flavour. This applies to the wild fruit. There are grounds, it appears, for hoping that under cultivation the quality will be improved. It is, says M. Martin, very accommodating as to the nature of the soil in which it grows, and Messrs. Vilmorin, without, of course, committing themselves to any opinion on the value of the plant or its chances of successful culture, recommend its trial in Southern Europe, Algeria, and some of the French colonies. We hope M. Martin will speedily furnish the means of determining the plant scientifically, and be the means of introducing it into some of our own colonies. The climatic difficulties in the way of its cultivation would seem to be less than in the case of the Soudan Vines, which latter we venture to think, will prove valueless in Europe.

— THE WEATHER.—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending March 27, issued by the Meteorological Office, London:—"The weather has been much less settled than late; rain, hail, or snow, has fallen in all places, and a thunderstorm was experienced in the south-east during the evening of the 26th. The temperature has fallen decidedly, and has been lower than for some considerable time. It was, however, still equal to, or slightly above, the mean. The maxima, which occurred at most stations on the 24th or 25th, varied from 53° in "England, N.W.," to 58° in "England, E.," and "Ireland, S." The thermometer was lowest during the first three days of the period, when the minima ranged from 26° in "England, S.," and 27° in the "Midland Counties," to 32° in "Ireland, S." The rainfall has been more than the mean in all districts except "Scotland, E.," the excess in the north-west and east of England being rather large. Bright sunshine, though it was still very general on some days, shows a decided decrease as compared with last week's amounts; the percentages varied from 53 in "Scotland, E.," to 20 in the "Midland Counties." Depressions observed:—"Pressure has been higher over the south-west parts of our area, while several depressions, some of which were deep, have travelled in an easterly direction across our islands. The wind has consequently been westerly to north-north-westerly, and, though moderate on most days, increased at times to a fresh or strong gale. The gale experienced on the 26th (Sunday) was very general, and in some places exceptionally severe.

— GARDENING APPOINTMENTS.—ALEXANDER McLEAN, from Messrs. DOWNIE & LAIRD'S Pinkhill Nursery, Edinburgh, has been appointed Head Gardener to SCISHAMMO, C. DE TRAFALD, Esq., Croston Hall, Lancashire.—MR. ROBERT DAVIDSON, from Dalkeith, has succeeded Mr. HALL (who has gone into business for himself) as Gardener to C. N. McDOYNE, Esq., at Wells, Gorey, Co. Wexford.—MR. W. EARP, lately Gardener at Popley Hall, Market Drayton, has succeeded Mr. WILMET as Gardener to C. S. ROUNDLELL, Esq., M.P., Osborne, Haslemere.

HOME CORRESPONDENCE.

Trickery in Plants.—Probably the same man mentioned by your Maidstone correspondent has lately been in the neighbourhood of Leytonstone, painting off his scented plants as genuine novelties. Some weeks ago he called at my house during my absence, and succeeded in selling his remaining stock of three plants, a trifling sum being given him in payment. These were potted and placed in a greenhouse, but, alas! soon became scentless, but continued growing for some time, until a fungoid growth happened to break out upon two of them, to the influence of which they eventually succumbed. As I had grave doubts as to the alleged value of the plants I was not greatly grieved at this result, more especially as I secured a quantity of the fungoid growth, which I found on examination to be a beautiful *Ecidium*, apparently *E. urticae*, a lovely object under the microscope; but as this good fortune may not fall to the lot of all purchasers it would hardly be worth while to invest in them on the mere chance of the fungus appearing. The third plant is still growing healthy, and will be retained until its identity is discovered. There is but little doubt, however, it is the same thing referred to in the paragraph in last week's *Gardener's Chronicle*—a dead Nettle. I may remark, *en passant*, that I read with very great interest the remarks upon Caladiums by Mr. Hart, as his evidence entirely corroborates my views, expressed in your pages some time ago. *G. F. Cox, Leytonstone.*

Roses Out-of-Doors.—It may interest your readers to know that we have here (South Ham) a couple of fully expanded and perfectly formed Roses, with numerous buds ready to open. The Rose is *Gloire de Dijon*, and occupies a sheltered position on the house. Has any other reader to record Roses flowering thus early (March 22)? *G. F. S.*

Tuberose.—These rank, as they justly deserve to do, among the choicest and most useful flowering plants which embellish our conservatories, drawing-rooms, and boudoirs during the summer, autumn, and early winter months, and to say that the individual blooms of the Tuberose—of which, roughly speaking, a spike contains two or three dozen—are almost equal to Gardenias, which flowers they slightly resemble, would be no exaggeration of their value, and the esteem in which they are held among those who have to do with the making and wearing of bouquets; and this is not to be wondered at, seeing that they possess qualities absolutely necessary in the composition of such floral ornaments—those of pearly whiteness and delicious fragrance, features which, in a general way, never fail to excite admiration. As a decorative plant the Tuberose, when associated with Ferns and other suitable plants, is very effective, but it is for the making of bouquets and buttonholes that its flowers are especially valuable and adapted, and for this purpose, owing to the order in which the individual flowers expand, are very accommodating in their habit, inasmuch as they only expand a few flowers at intervals of a few days at the bottom of the panicle, and so on, until the topmost flower is developed, and on this account a dozen plants in this stage of floral development would, for the purpose above indicated, yield a moderately good supply of flowers for four or five weeks at a stretch, even one of which, as they wear well, may be turned to account. And by potting a dozen tubers more or less, according to circumstances, at intervals of a fortnight or three weeks from the beginning or middle of March to the end of June, the supply of these chaste flowers may be extended from June to Christmas. The Pearl, a dwarf American variety, from 2 to 3 feet high, is the best to grow, and should be potted in 3-inch pots, burying three parts of the tuber in the soil, which should be a sandy loam with a little leaf-mould added, and previous to being potted the tubers should have the old fibrous roots cut away, and all the little bulblets or offsets rubbed off, and subsequently any suckers which may appear should be removed forthwith, otherwise failure to flower in all probability will be the result. The soil must be kept on the dry side until the flower-stem appears, and when the latter is about 6 inches high the plants, being sufficiently moist at the roots, should be shifted into 6-inch pots—their flowering pots—and water withheld from the roots for a few days until the latter have taken hold of the new soil; and as the pots become filled with roots, liquid manure in a weak state should be given them; this will tend to the production and development of finer flowers. In conclusion, I would remark that as soon as the tubers are potted the pots should be plunged to the rim in a Melon or Cucumber frame

to start them into growth, and subsequently the plants should be grown on near the glass to insure a sturdy habit. *H. W. W.*

Cantua dependens.—This is seldom met with, but as a choice climber for a cool house it deserves more attention. Trained up one of the pillars in the conservatory at Belton House, near Grantham, it shows its bright crimson flowers off to perfection, and at once strikes the eye of the spectator as something out of the ordinary way and deserving of more general cultivation. *W. H. Divers, Burghley.*

A Reflex Garden Seat and Table.—Messrs. J. J. Thomas & Co., 87, Queen Victoria Street, E.C., are about to introduce to public notice a new

FIG. 68.—GARDEN SEAT.

patent garden seat and table, brought out by Mr. Samuel Mead, which, unlike many other combinations which are more ingenious than useful, has the merit of being a really useful contrivance. It is a

FIG. 70.—GARDEN SEAT AND TABLE.

most comfortable seat, with arms and sloping back, which by a movement of the simplest character can be converted into a seat with a steady and substantial table in front of it. Under the seat there is a com-

FIG. 71.—SEAT WITH AWNING.

modious locker for holding croquet or lawn tennis balls, garden tools, &c. The mechanical details are exceedingly simple, the movable parts securing themselves automatically by their own weight.

Proliferous Pine.—The illustration of a prolific Pine-apple, in your last week's issue, reminds me of a similar one I fruited when at the Crystal Palace in 1857. It may be remembered that the Crystal Palace Company purchased the whole of the Messrs. Ludlows' collection of plants at the Hackney Nursery, and this plant formed one of the collection. It was then but a small sucker, and was in our possession about three years, when it produced its extraordinary conglomeration of fruits. I find, on referring to my diary, that I took it up to 21, Regent Street, on February 19, and showed it to the late Dr. Lindley, who was much pleased with it. He also examined several drawings of Penang Pine-apples in his possession, but they all differed considerably from the one I took him. Dr. Lindley wrote an

article on this curious fruit in the *Gardener's Chronicle*, where it may be found in the number for February 28, 1857, p. 132. *Geo. Eyles.* [It should have been stated that we were indebted to Messrs. Low, of Clapton, for the photograph whence our illustration was taken. Ed.]

The Araucaria in the Island of Mull.—I noticed in the *Portsmouth Constitutional* lately a memorandum of the dimensions of the Araucaria at Keir, which is represented to be "the finest specimen of its kind in Scotland." I think, however, we have one at Duart, in the Island of Mull, which, so far as girth is concerned, is better than that at Keir. Here are the dimensions:—

	Keir.	Duart.
Height	44 ft. 3 in.	39 ft. 0 in.
Girth 1 foot from ground	5 4 1/2	6 0
Girth 3 feet from ground	4 8 1/2	5 10
Girth 6 feet from ground	4 4	5 6

The Duart specimen is a female, and about ten years ago the leader became sluggish, and seemed to make no progress for five or six years, but within the last five or six years it has begun to shoot upwards again. Is there a finer Araucaria in Scotland than this specimen at Duart? *Fraser Sim, Oban.*

The Flowering of Peaches and Nectarines.—Most of these, as is well known, are naturally very early in flowering and it would, I think, be a great gain, when they are grown outdoors, if we could have sorts that open their blossoms later, as a few days or a week often makes a vast difference in their setting, and those sorts that keep their tender organs covered the longest invariably stand the best chance. All our trees being on the same wall facing east-south-east, we have a good opportunity of testing and noting the difference in the forwardness or otherwise of the several varieties; and taking advantage of this, I went carefully over them on the 14th of March to see which were the most advanced, and found them as follows:—Bellegarde Peaches had, as nearly as could possibly be estimated, about one-third of their blossoms open, Noblesse fully a half, Goshawk ditto, Dr. Hogg a fourth, Poupree Hative 5 per cent., Stirling Castle two-thirds, Late Admirable none, Grosse Mignonne half, Early Rivers 4 per cent., Warburton Admirable 5 per cent., Early Allent a quarter, Malva a half, Leve Palmerston one-third, Barmington about 2 per cent., Eagle Nectarine one or two flowers only fully open, Fine-apple 3 per cent., Humboldt ditto, Lord Napier none, Imperatrice none, Pitmaston Orange one-fourth. It is rather remarkable that the earliest and best Nectarine, which Lord Napier is, should lag behind, and this is another important point in its favour. Since taking my notes they have come on with a rush, the weather having been all that could be desired, except that we have had some rather sharp frosts by night, but the land and everything being so dry and the atmosphere so still they have not met the least harm, and I look forward to having one of the best fruit seasons we have had for years past as regards Peaches, Nectarines, and Apricots, as the flowers are remarkably strong and bold, and the aubers full of ripe pollen. With the sun warming up the walls and the dry buoyant air this cannot fail to disperse and perform its allotted part, as indeed it has done in a great measure already, for on the most forward trees petals are falling, thus showing that fructification has taken place, and that the most critical period is over. Apricots have been a sight, and if to per cent. of the blossoms set and the fruit swells we shall have to thin, so full and gay were the trees a short time ago. Weather prophets have been predicting all sorts of evil things about what is to come, and that we are yet to suffer for the mildness of the winter, but we can only hope that their predictions may, as usual, be falsified, and that the seasons have changed in our favour. *J. Sheppard.*

Fruit Prospects.—People are now asking what kind of fruit crops there will be this coming season. This is a question that cannot be answered at present, so much depending on the weather we may have during the next two months. After a most remarkably mild winter, the spring has set in with very boisterous cold weather. On Tuesday, March 21, we had showers of hail, rain, and snow, at short intervals the whole of the day, accompanied with cutting winds, and at night quite a sharp frost. On Wednesday the wind got round more to the north, and was very cold and piercing the whole day. Apricots and Peaches are in full flower; the former are not setting very well, much of the blossom is falling off, so that the crop will not be abundant here. Some trees promise better than others, the maturation of the wood last autumn having much to do with it. Peaches are promising well, the blossoms being abundant and appear to be setting. Pears and Apples do not promise an abundant bloom. Pears here are best on

standards. Some of the pyramids have a nice show of buds, but many of the trees have very little. Fears on the walls promise only moderately. Some Apple trees promise an abundant bloom, but trees in general do not. Plums will have an abundant bloom, and will be a heavy crop if trees are not injured by the frost. Cherries also promise to be abundant. Gooseberries are fast coming into bloom, but if the severe weather we are experiencing at present continues, I fear the crop will suffer. Currants are not very far forward considering the mild open weather we have had, so that there is a prospect of a good crop. Strawberries look well and promise an abundant crop. Up to the 21st March, everything was promising very fairly on the whole, but the sudden change to the severe weather of the past few days has changed for the worse the aspect of affairs. The outlook, at present, is not very cheering, for should we have more or less of this cold weather for the next two months, it is certain to do much injury. *M. Saul, The Gardens, Stourton Castle, Yorkshire.*

Nicotiana affinis.—The following experiments were lately made with this plant, with a view of ascertaining the best time for its flowers to be influenced by light under natural conditions they close about 8 P.M., and open again about 6 P.M. On March 18, plant No. 1 was brought into artificial light at 10 P.M., when it was fully expanded; it remained so till 11 P.M., when the light was put out; it was wide open at 6 next morning, but closed about the usual time; it was then put into a dark room, but failed to open its flowers; at 9 P.M. it was placed in artificial light until 10.30 P.M., but did not open; it was then placed with the other plants, and at 6 next morning was in the same condition as they were, but remained partly expanded all day, whilst the others closed as usual. Plant No. 2 was taken on March 20 at 6 A.M., when all were expanded, and placed in a dark room, but closed up at the usual time; it remained closed all day, but at 10 P.M. was partly open, and at 6 next morning was fully expanded, and remained so three days and two nights; on the third day, at 7.30 P.M., it was placed in artificial light until 11 P.M., during which time it remained closed, but opened, owing to the influence of the light slightly; the light was put out at 11 P.M., and at 6 next morning it was still open; it was then placed in full daylight with the others, which closed about 8 A.M., as usual, but this one remained open still; at 10 A.M. it was only very slightly closed, and the same at 12 A.M.; at 10 P.M. all were again alike, but since then this one and Nos. 1 and 3 have remained expanded two hours longer than the others, and opened again about two hours sooner, and have not closed up so much as the others which were not experimented on. No. 3 was taken from the others on March 20, at 2 P.M., when its flowers were closed, and placed with No. 2 in a dark room; it remained closed, and opened at 6 P.M., the same as those under natural conditions. It was open at 10 P.M., and 6 next morning, but closed same time as those in the daylight, though not shutting up quite so close. At 11 P.M. it was still in the same condition. At 6 next morning it was open, and remained so two days and one night; it was then taken into artificial light along with No. 2, and has behaved exactly the same as that one since. The scent is very powerful, and approaches that of the Honeysuckle, but is nearly absent during the daytime, even from those that are fully expanded. All three of the plants that were experimented upon show a tendency now (March 28) to remain open through the day, and continue to close two hours later in the evening, and to open two hours sooner in the afternoon. *W. H. Divers, Burgessley.*

Bees in Peach-houses.—It would be very interesting to many, like myself, who value their bees, to know how those employed by Mr. Muir in his Peach-house (see p. 408) will do this summer. My own experience of the system, after several seasons' trial, leads me to prefer, as more economical, hand-fertilising with a brush, or what is perhaps better, a small bunch of soft downy feathers tied to a rod, with which one can go over a large tree in a very short time. Bees are often so much weakened by being used in Peach-houses that they become useless for that season or die outright. I have always found when bees are taken under glass that a great number of them die through exhaustion consequent on their struggling against the glass roof endeavouring to fly upwards—a well-known instinct in bees, as they always, on finding themselves in new quarters, soar upwards in a spiral manner to take the bearings before flying away. The loss of honey and pollen, and loss of bees at this season is more damaging to a hive than probably at any other, as their activity on finding themselves in warmer quarters induces the queen to lay eggs freely, and there being no young bees as yet to hatch and feed the brood this duty falls on the old, besides having to provide honey as well as pollen and water for the young. This, to my mind, as well as the check they receive on being turned out-of-doors, account

for my want of success, and I have known other gardeners who had the same experience, so that to those who love their bees hand-fertilising would be quite as economical. *H. Henslow, Hull Place, Crawley.*

Civic Science.—The City of London has an excellent library, and a learned and most courteous librarian, at the Guildhall. The City also has a small semi-subterranean museum in or under the same building; some of the museum objects are visible; a considerable number no one can possibly see; some objects are antiquarian, others are truly civic. In a small room just upstairs to the left from the museum civic science has a choice niche. Modestly placed with its back to the window (the light is never overpowering at the best of times) is a tall and handsome glass case. The case contains, at the bottom, a lump of sponge, and springing through the sponge is a Horny Coralline, *Hydroid*, or *Aleyonarian scopophyte*—quite an everyday and commonplace affair. This case bears a remarkable inscription, painted on a tablet of deal (neatly grained to imitate Oak)—the legend says in capitals "This sponge was dredged in the Bahamas." Then in small Roman letters young citizens are instructed in the following terms:—"It shows the indissoluble union of an Animal (the Sponge) and a Vegetable (the Marine Plant). The sponge has affixed itself to the root of the plant, and both have grown together, the branches of the plant transfusing the sponge." On the left of the case is a coloured view of the City of London Fish Market, and on the right the Meat and Poultry Market, and, eke, the Provision Market, or animal and vegetable and science and art all combined. On Tuesday I asked the beadle if he had not got a model of the Temple Bar Memorial: he said it was in the Great Hall. I went to the Great Hall, and there asked another beadle. "Sir," replied this functionary, "yes, we have got a model of the Temple Bar Memorial, but it is not visible to the public." *W. G. S., April 1.*

Reports of Societies.

Royal Horticultural. *March 28.*—Colonel Trevelyan sat in the chair. The Rev. G. Henslow commenced his lecture by calling attention to the differences between the two families Liliaceæ and Amaryllidaceæ—the magnificent series of Hyacinths and Tulips, Squills, &c., illustrating the former, while Messrs. Barr & Sugden's series of Narcissi, Amaryllides of Messrs. Veitch, &c., as well as the specimen of *Doranthus* from Kew, illustrated the latter—easily recognised by the ovary of the flower being below it in Amaryllids, but free and within the tube in Lilies and their allies. *Dicentra spectabilis*, through misapprehension of the name of this plant, has been changed to *Diclytra* and *Diclytra*, but *Dicentra*, which means "two spurs," is correct. Mr. Henslow explained how it is fertilised by bees, which remove the little clapper-like petals and so expose the stamens and pistil on searching the flower for honey. The most remarkable instance of insect fertilisation, however, was furnished by the curious *Orchid* exhibited by Sir T. Lawrence, called *Coryanthes macrantha*, from the West Indies. In this the labellum is shaped like a boat or tub, but attached at the lower end by a stout and bent support, thus forming a powerful spring. The column, which bears the stigma and anthers, projects over the boat, the two having their ends in contact. Two hornlike processes projecting from the column continually secrete water, which is caught by the boatlike labellum. Insects, such as large bees, are attracted by the sweet ridges or wringlike expansions at the basal end of the labellum; the food thus obtained appears to be stimulating or intoxicating. The result is that the bees push one another down into the boat, their wings become wetter, so they cannot fly out; but can only escape by crawling along the bottom of the boat and squeezing themselves between the "bows" of the boat and the end of the column. The first insect which escapes invariably carries off the pollen masses. But in order to fertilise a flower it must repeat the process, take a second bath, and escape as before; but on this occasion it sneezes the pollen upon the stigma. The lecturer next called attention to some new hybrid *Rhododendrons* exhibited by Messrs. Veitch. He observed how in this flower, as in *Pterolanthus* and *Gloxinia*, which are irregular flowers in the wild state, are becoming regular under cultivation; and the stamens, instead of inclining downwards or being "declinate," spread symmetrically round, the petals being also uniform, instead of having one in the form of a "lip."

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker, K.C.S.I., in the chair.

Earl of Romney's Plants.—Mr. W. G. Smith reported his examination of these. He said the *Primroses* were attacked by the fungus known as *Leidum primulae*, a pest confined to *Primula*. The *Carnations* and *Pinks* were attacked by the nematoid worm *Tylenchus*, recently illustrated in the *Gardener's Chronicle*, and with *Puccinia lychnidum*, a parasite peculiar to the *Lychnis* tribe. The *Narcissus* leaves were suffering from attacks of a leaf-boring larva. The abnormally mild winter had no doubt been favourable to the existence and early re-appearance of various animal and fungus parasites of plants. There need be no apprehension whatever that these pests would spread to cereal and root crops in the neighbourhood, as the plants sent were not attacked by one enemy, but by many, and each peculiar to the plants attacked.

Thallogous Leaf.—There was no trace of fungous-work on this leaf, fungi being comparatively rare amongst *Orchids*, neither were traces of insects to be seen. There was a marked deficiency of parenchyma in the leaf, possibly pointing to some weak point in the cultivation.

Fungus on Living Insect.—Mr. Pascoe showed specimens of a beetle from Queensland, named *Saragus fuscus*, the specific name having been applied before it was ascertained that the woolly appearance was due to the presence of a fungus. It had been doubted whether fungi really occurred on living insects, but the present specimens were captured upon trees affected with an *Isaria* identified by the late Mr. Currey.

Labels for Plants.—Mr. G. F. Wilson showed Foxwood labels which, as already stated, are objectionable from their tendency to become covered with mould, but which might be avoided by steeping the labels prior to use in hot paraffin. Mr. Lynch showed labels of zinc of various forms suitable for the different purposes, and also others made of stout slabs of so-called "Inch-ine," which is very durable, and can easily be written upon.

Rhododendrons.—Mr. Mangles showed fine trusses of *R. grande* (sine argenteum). The plant was discovered in Sikkim by Sir J. (then Dr.) Hooker, and in *Boota* by Griffiths. The flowers are magnificent, bells of creamy-white, with a delicious fragrance, the parts arranged in eights, and the foliage noble.

R. fornesium is a native of Cachcar, and therefore more tropical in its character. The flowers are pure white, and widely campanulate. It is nearly allied to *R. Veitchii*, with which it will interbreed, and is one of the parents of *R. sesterianum*.

R. Connorsii of *Himalayana*.—A lovely hybrid, with large pale rose-lilac tubular corolla. It is a cross with the pollen of *R. Dalhousie* or *R. ciliatum*. Mr. Mangles remarked that he had invariably failed in his attempt to reverse the cross by fertilising *Dalhousie* with *ciliatum* pollen.

R. campylocarpum.—A species rarely seen, bearing clusters of sulphur yellow flowers, which Sir Joseph Hooker noted as remarkable for the freedom with which they moved when agitated by the wind.

R. Veitchianum (from Mr. Hermann Rucker).—A native of Moulmein, with widely campanulate deeply lobed flowers, with crisped edges to the segments; the colour white, with a golden throat.

R. Dalhousii.—A noble species, the large funnel-shaped flowers of which are of a sulphur-yellow colour produced in this country, but are figured as white in Sikkim.

R. jasminiflorum.—A tubular-flowered species from Malaya, so different from most *Rhododendrons* that when first seen its identity was questioned. It was noted as a curious fact that the Malayan species of *Rhododendron* did not interbreed with the *Himalayan* varieties.

R. Princess Alice.—A hybrid between *R. Edgeworthii* (male) and *R. ciliatum* (female).

An unnamed hybrid between *R. Thomsonii* (Sikkim) male, and *R. Fortunei* (China), female, with the brilliant scarlet colour of *Thomsonii*, but with larger and more numerous flowers, and with the foliage of *R. Fortunei*.

Other hybrids were shown between *R. ciliatum* and *R. glaucum*, as well as some sent to Mr. Mangles by Messrs. Downie & Laird, of Edinburgh.

The Hon. and Rev. J. Townsend Boscewen sent an interesting hamper of hardy hybrid *Rhododendrons*, which Mr. Mangles commented on to the committee. A very beautiful white hybrid was very conspicuous, and was much admired. It is called hardy. A better white has not been raised.

Crimson, claret, very dark purple, and blush, were all represented, and some of the trusses were very large and finely formed. A brilliant scarlet raised some discussion as to whether it was not a form of the true *K. arlorum*. The vividness of the colour was quite equal to the colour of the true species. Some others were very closely allied to the *Himalayan* species, and some almost identical.

Plants, &c., Exhibited.—Mr. Lynch, of the Cambridge Botanic Garden, brought flowers of *Begonia Roezlii*, a fine free flowering species with glabrous obovate fleshy leaves and large eyes of rosy-crimson flowers. *Ribes cereum*, an insignificant species from North-West America, *Primula carpatia*, a small species in the way of the true *P. elatior*, with a distinct aromatic perfume similar to that of *P. sikimensis*. *Cheiranthus mutabilis*, which this season has bloomed out-of-doors; the original form of *Cheiranthus Chirii*, *Hibbertia Reelii*, *Candollea tetrandra*, *Arctotis aspera arborescens*, *Asarum caudatum*, a Californian species with flower segments prolonged into long slender tails. From Miss Mangles came *Tulipa Celsiana*, *T. oculus-sois* var. *præcox*, *T. platystigma*, *T. Loretii*, with narrow flower segments, crimson with a dark basal spot edged with yellow; *Lavandula Stechas*, *Mesembryanthemum acinaciforme*, *Bougainvillea speciosa*, of remarkably rich colour. All these came from Cannes.

From Sir J. Hooker came a leaf and a portion of the inflorescence of the stately *Doranthes Palmeri* now flowering at Kew, and described in our last number. Among other plants exhibited were *Primula obconica*, with trusses of pale lilac flowers well raised above the roundish caliculate leaves; *Maxillaria callichroma*, with linear white flower segments tinged with yellow, the small lip whitish, with narrow crimson stripes; *Myrica stipitata*, from Mr. C. Green, gr. to Sir G. Macleay, at Pendell Court, with broad oblique rough leaves, and very long thread-like branching pendulous inflorescence studded with minute green flowers. Mr. George, of Putney, showed variously deformed leaves, some peltate, from a plant supposed to be a cross between an Ivy-leaf and a zonal *Polygonum*. The feasibility of this cross has been doubted, and Mr. Mangles related that his attempts to cross these two varieties had uniformly failed. Sir Trevor Lawrence showed his *Coryanthes macrantha*, a Stanhope-like *Orchid* of the most extraordinary structure and remarkable history, alluded to by Mr. Henslow in his lecture. As we intend to give an illustration of this plant in a future number we defer further comment for the present.

SPRING SHOW.—The first show of the season, held in the conservatory, was a very enjoyable one, there being a capital display of Hyacinths and other gay flowering plants, and a good attendance of visitors. The leading feature of the show, the Hyacinths, we have dealt with in another place, so that we need not here enter into critical details. Messrs. James Veitch & Sons received a Silver-Gilt Flora Medal for a fine group of over 200 pots of Hyacinths, and awards of a similar value were accorded to Messrs. Osborn & Sons, Fulham, for one of the best groups of Hyacinths they have ever exhibited, and in conjunction with which were groups of Tulips and Narcissis, and forced *Chionodoxa*; to Messrs. Barr & Sunden for immense assemblages of cut flowers of Dahlias and other spring flowers overcrowded and badly shown in admixture with various forms of Kales—an ill-assorted match; and to Mr. R. Clarke, of Twickenham, for a grand display of Cyclamens, splendid strain of *C. persicum*, including the pure White Superb, a model of what a pure white decorative variety should be. Silver Flora Medals were awarded to Messrs. Wm. Cutbush & Sons, Highbate, for a capital group of Hyacinths, Tulips, and Indian Azaleas, accompanied by half-a-dozen boxes of cut flowers of Camellias; to Mr. B. S. Williams, for a very showy group of plants, including a number of Amaryllis, a fine specimen of the brilliant orange-scarlet coloured *Imantophyllum miniatum* var. *Martha Keimera*, and a quantity of Orchids in bloom, mainly well known sorts; to Messrs. H. Lane & Son, Berkhamsstead, for a beautiful group of forced *Rhododendrons* and *Ghent Azaleas*; to Messrs. H. Williams & Sons, Fortis Green, Finchley, for a group of very good *Primulas*, Hyacinths, and Tulips; to *Stilpn* some showy Auriculas, Col. Champneys and Chas. J. Perry; and Mr. Sidney Ford, Leonardale, Horsham, had about sixty dishes of very well preserved Apples.

Prizes were offered by an amateur in Amaryllis, in three classes, for his favourite flowers, but there was no competition. The 1st prizes in each class were taken by H. Little, Esq., whose six consisted of Leah, Orpheus, Queen Victoria, Hereward, Stella, and Drapeau Royale. His best seedling was Hercules, a medium-sized pure scarlet; the best light-coloured variety, Orpheus, white ground with scarlet venation; and the best dark seedling, Hereward, a dark crimson of poor form.

A Fellow of the Society offered prizes for the best

nine pots of Hyacinths and Tulips, but here also there was no competition, the 1st prize being taken by Mr. Douglas, gr. to F. Whitbourn, Esq., Loxford Hall, who had neat and good spikes of Mont Blanc, Vurbak, Grandeur à Merveille, Baron Von Tuyl, Von Schiller, King of the Blues, and La Grandesse; and of Tulips, a good pot of *Joost van Vondel*, Prosperine, White Pottebakker, Keizer Kroon, and Vermilion Brilliant, &c.

FLORAL COMMITTEE.—Rev. H. Harpur-Crewe in the chair. Messrs. James Veitch & Sons were large exhibitors of new plants on this occasion, principally of Hyacinths, Amaryllis, and *Rhododendrons*. Of the former, there were nineteen climates for distinction, but only four were certificated, viz., Enchantress, single blue, with a bold spike of fine bells, of a lilac ground colour and lavender-blue shading; Delicata, large, broad, and stout bells, of a delicate flesh colour; Leo, a double form of the last, being of the same colour, but having immense full double bells, and powerful odour; and Challenger, single, a very dark claret, shaded with dark crimson. The new certificated *Rhododendrons* were *R. Favourite*, a flower of moderate size, good form and substance, and rose-pink in colour; and *R. Aurora*, a large flower, of good form and orange-salmon in colour. The best of the Amaryllis were *The Giant*, a variety of extraordinary size, bearing three stems about 3 feet long, on which were not less than sixteen flowers, white ground, with flakes and stripes of crimson; and *Duke of Albany*, a very beautiful pure scarlet flower, with white a centre, and excellent in form and size. The same name also exhibited *Leea amabilis*, probably a climbing plant, but as shown in a dwarf state the leaves are unequally pinnate, the segments lanceolate, acuminate, serrated, purplish-bronze, with a central silver stripe on the upper surface. *Pinguicula caudata*, the same as the *P. bakeriana*, shown last year by Messrs. Sander & Odontoglossum Pescatorei Veitchii, the finest novelty shown amongst Orchids, having flowers 2 inches across, nearly circular, the flower segments broad, white, heavily barred and spotted with brown. Messrs. Hugh Low & Co. had *Phalenopsis Stuartiana* and *P. Stuartiana nobilis*, a variety of the same colour and markings, but larger in all its parts than the type. Mr. Woolford, gr. to W. Lee, Esq., Downside, Leatherhead, showed splendid forms of *Odontoglossum membranaceum roseum*, in which the flowers are rather deep lilac instead of white; *Masdevallia Shuttleworthii*, *Odontoglossum Chestertonii* and *O. Cervantesii* de brown, with white segments marked with purplish-brown. From Mr. H. Parr, gr., Givon's Grove, Leatherhead, came two very fine plants of *Corylogne ocellata*, bearing a dozen spikes or so each; and from Sir Trevor Lawrence's garden came the extraordinary *Coryanthes macrantha*, alluded to elsewhere; also *Odontoglossum asperum violaceum*, sepals and petals lanceolate, the former heavily blotched with brown, the latter yellowish, plumed at the base, lip flat, cordate acute, pale violet; and *Masdevallia Shuttleworthii* and *Masdevallia*, a small variety with dark green, leathery, oblong leaves, tapering into a long slender stalk, the flower segments shell-shaped, prolonged into long slender tails, and in colour yellowish, marked with narrow purplish stripes or thickly dotted with minute purple spots. The striking *Doranthes Palmeri* was represented by a leaf and a portion of the flower-stem, sent from Kew. Mr. Salter, gr. to J. Southgate, Esq., Streatham, sent *Maxillaria callichroma*. The General Horticultural Company showed *Adiantum Victoriae*, one of Mr. Basse's seedlings, said to be between *A. decorum* and *A. scutum*, but really resembling a very dwarf erect-growing *A. farleyense*, and a decorative plant of sterling value. A basket plant of *Lycaste Skinneri* bearing a dozen large pure-coloured blooms, came from Mr. W. G. Gaiger, gr. to T. Taylor-Whitehead, Esq., Burton-Closes, Bakewell. Mr. Anthony Waterer sent from Knap Hill some well flowered plants of *Deutzia candidissima* and *Andromeda japonica*, which forces well; and *Andromeda japonica*, a new species with large drooping panicles of white blossoms and dark green leathery ovate-acute leaves. A few *Abutilons* of the dwarf section alluded to at p. 370 were again shown by Mr. George; and *Primula obconica*, a new introduction from China, came from the Messrs. Veitch. It has pale pea-green hairy leaves and leaf-stalks, and mauve-pink flowers freely produced in the way of *P. cortusoides*. The live variety of *Myosotis distillifera*, known as splenders, came from Chiswick, and Mr. Dean, gr. to the Lincen Gower, Esq., had a pure white form of the same plant. Mr. Green, gr. to Sir Geo. Macleay, brought up from Pendell Court cut flowers of *Myrica stipitata*, referred to in the report of the Scientific Committee, and *Antholyza bicolor*, an Iridaceous plant with a slender spike of elongated curved cylindrical orange and green flowers. Messrs. H. Cannell & Son showed a plant of *Cineraria Victoria*, a very fine purple-rose-tinted self of great size, and a fine form of a bouquet of yellow and white *Marguerites* mixed with *Cineraria cruenta*, and forced

plants of *Spiraea Sieboldii*. Mr. H. Bennett, of Shepperton, showed his hybrid *Tea Rose*, Her Majesty, a seedling from Mabel Morrison—a light pink or light peach-coloured flower of beautiful form, but not so scented; and his fine dark Earl of Pembroke, which on the other hand has a delicious perfume. Messrs. Paul & Son, Cheshunt, also had a new Rose, Helen Paul (Lacharme), a variety with large white flowers remarkable for the size of the petals; also a good dark rosy-purple *Primrose* in *Primula aculis* *Crossii* *flore-pleno*. Captain Patton showed a collection of new Tulips, and the Continental Horticultural Company, Ghent, showed *Gynura aurantiaca*, a plant grown in this country forty years ago, and very pretty in a young state, but of doubtful value at present as a bedding plant, for which purpose it is being recommended. *Spergula pilifera aurea*, a good, constant, hardy golden carpet bedding plant, came from Mr. R. Dean; and a hose-in-hose *Richardia* came from Mr. Phillips, gr. to Captain Jackson, Meopham, Kent.

The awards were:—

First-Class Certificates.

To Messrs. Veitch & Sons, for Hyacinth Leo.
To Messrs. Veitch & Sons, for Hyacinth Enchantress.
To Messrs. Veitch & Sons, for Hyacinth Delicata.
To Messrs. Veitch & Sons, for Hyacinth Challenger.
To Messrs. Veitch & Sons, for Amaryllis The Giant.
To Messrs. Veitch & Sons, for Amaryllis Duke of Albany.
To Messrs. Veitch & Sons, for *Rhododendron Favourite*.
To Messrs. Veitch & Sons, for *Rhododendron Aurora*.
To Messrs. Veitch & Sons, for *Leea amabilis*.
To Messrs. Veitch & Sons, for *Pinguicula caudata*.
To Messrs. Veitch & Sons, for *Odontoglossum Pescatorei Veitchii*.
To Messrs. Veitch & Sons, for *Primula obconica*.
To the General Horticultural Company, for *Adiantum Victoriae*.
To Mr. Woolford, gr. to W. Lee, Esq., for *Masdevallia Shuttleworthii*.
To Mr. Woolford, for *Odontoglossum membranaceum roseum*.
To Mr. Anthony Waterer, Knap Hill, for *Andromeda japonica*.
To Mr. H. Bennett, for *Rosa Her Majesty*.
To Mr. Spyers, gr. to Sir Trevor Lawrence, for *Coryanthes macrantha*.
To Messrs. Paul & Son, Cheshunt, for *Primula aculis Crossii flore-pleno*.
To Messrs. Low & Co., for *Phalenopsis Stuartiana* var. *nobilis*.

Cultural Commendations.

To Mr. H. Parr, for *Corylogne ocellata*.
To Mr. W. G. Gaiger, for *Lycaste Skinneri*.
To Mr. Anthony Waterer, for *Deutzia candidissima flore-pleno*.
FRUIT COMMITTEE.—H. J. Veitch, Esq., in the chair. The only subject brought before this body was a curled Kale, shown by Mr. J. Reed, Mount Mount, Mill Hill, Hendon, and which was stated to be the result of a cross between *Conve Tronchuda* and Veitch's Dwarf Curled Kale [?]. The committee requested that it be sent to Chiswick for trial.

Royal Botanic: *March 29.*—This Society opened its campaign on Wednesday with an exhibition much superior in point of merit to many of its predecessors. Large groups of Hyacinths and Tulips, Cyclamens, *Cydonias*, *Rhododendrons*, plants new to the public, and common, from stove and greenhouse, all combined to render the corridor and large conservatory unusually gay; while in the adjoining stove there was a plant of the lovely *Petrea volubilis*, in magnificent bloom, and vying in beauty with any of the more modern notabilities close by. The display of Hyacinths included all the collections shown at South Kensington on the previous day, the exhibitors being Messrs. Veitch & Sons, Messrs. Osborn & Sons, Messrs. W. Cutbush & Sons, Messrs. H. Williams & Sons, and Messrs. James Carter & Co.; and in addition to these plants staged in the hands of the amateurs' and nurserymen's classes for twelve. In the former class Mr. James Douglas was again to be found with bold substantial spikes of *La Grandesse*, *De Candolle*, *Fabola*, *Blondin*, *King of the Blues*, *Macanilly*, *General Havelock*, *Von Schiller*, *Grandeur à Merveille*, *Car Peter*, and *Koh-no-rod*; Mr. H. Eason, gr. to B. Noakes, Esq., North Hill, Highbate, was 2d. Messrs. W. Cutbush & Son came in 1st among nurserymen, the varieties staged by them being *Macanilly*, *La Grandesse*, *De Candolle*, *Blondin*, *Mont Blanc*, *The Sultan*, and *Von Schiller*; Mr. Osborn & Sons were a good 2d, and Mr. S. Hill 3d. Fine examples of *White Joost van Vondel*, *Vermilion Brilliant*, *Prosperine*, and *Keizer Kroon*, from Mr. Douglas, also came in 1st in the amateurs' competition with twelve Tulips; next to him being Mr. Boulwood, gr. to Captain Patton, and Mr. H. Eason. In the nurserymen's class, Messrs. Osborn & Sons turned the tables on the Highbate firm, who was here placed 3d, Mr. S. Hill coming in 2d. For a dozen pots of *Narcissis*, the Messrs. Osborn & Sons were 1st, Mr. Hill 2d, and Messrs. Gregory & Evans, Sidcup, 3d, the leading varieties being *Jaune Supreme*, *Lord Canning*, *Grand Monarque*, *Sir Walter Scott*, and *Soleil Brilliant*. The *Primula* class calls for no comment save that, considering the lateness of the season, the 1st prize group from Messrs. H. Williams & Sons were a very creditable lot. The Cyclamens, on the other hand, were a grand class,

the plants all being of large size, with clean, vigorous foliage, and an abundance of clearly coloured, handsome blossoms. The first prize lot, staged by Mr. Wiggins, gr. to H. Little, Esq., were in that grower's best style; and he was very secondly by Mr. H. E. Hason, of Ealing, Deon, Mr. J. G. Gould's Green, H. Hingling, gr. to H. Little, Esq. In a class confined to anthers Mr. Wiggins had no opponent. The Anaryllis, hardy Primulas, and hardy heriaceous plant classes were not up to the mark, but the one for six Deutzias brought out a very meritorious lot of plants, especially a half dozen from Mr. Douglas that were perfection itself, the specimens being of cylindrical form, about 4 feet high, from 2 to 3 feet through, and densely bloomed. Mr. Wiggins was 2d, and Mr. H. Eason 3d. The Azalea classes brought out amongst others a very pretty half dozen of dwarf hybrids, well bloomed, from Messrs. B. Peed & Son, Streatham; and in a capital class of Lily of the Valley Messrs. H. Williams & Sons, Messrs. Gregory & Evans, and Mr. Douglas were the prize winners. For twelve stove and greenhouse plants Messrs. B. Peed & Son were 1st, with a very lot of small plants in a hothouse class from Mr. W. G. Wheeler, gr. to Louisa, Lady Goldsmid, being a very good 2d, and Mr. R. Butler 3d. There was only one exhibitor of Lachenalia's, Mr. H. Eason, but his were a splendidly grown dozen pots, full of L. luteola, and he was most worthily awarded the 1st prize. The miscellaneous class, always a large one here, included, besides the large groups of Hyacinths before named, collections of new and rare plants from Messrs. Veitch & Sons, Mr. E. S. Williams, and Mr. Wm. Bull, many of which were certificated as recorded below; a large and handsome collection from Mr. H. E. Hason; Rhododendrons, and Ghent Azaleas from the Messrs. Lane & Son; a dozen well-flowered decorative Pelargoniums from Messrs. Gregory & Evans; two boxes of Marchal Niel and one of Tea Roses, and plants and cut flowers of the new Toyonias from Esq., A. C. Oldfield, Bickley; a collection of Hyacinths and Tulips, from Mr. Boutwood, gr. to Captain Patton; seven boxes of fine cut Roses, from Mr. Rumsey, Joyning's Nursery, Waltham Cross; succulent plants from Mr. Bolter, &c.

The awards made to new plants were:—

Botanical Certificates.

To Messrs. Veitch & Sons, for *Odontoglossum Pescatorei* Veitchii.
To Messrs. Veitch & Sons, for *Odontoglossum Leeanaum*.
To Messrs. Veitch & Sons, for *Dendrobium Falconeri* giganteum.
To Messrs. Veitch & Sons, for *Cypripedium calceolium*.
To Messrs. Veitch & Sons, for *Lera* analabica.
To Messrs. Veitch & Sons, for *Chamaecyparis Kalmeyana*.
To Messrs. Veitch & Sons, for *Asparagus plumosus nanus*.
To Messrs. Veitch & Sons, for *Prinnula obconica*.
To Messrs. Veitch & Sons, for *Pinguicula caudata*.
To Mr. B. S. Williams, for *Phlox paniculata* *micrantha*.
To Mr. B. S. Williams, for *Adiantum latifolium*.
To Mr. B. S. Williams, for *Dielenia lucida* majestica.
To Mr. B. S. Williams, for *Asparagus plumosus nanus*.
To Mr. B. S. Williams, for *Zycopeltaria Clavii*.
To Mr. W. Bull, for *Odontoglossum Halli* nigrum.
To Mr. W. Bull, for *Odontoglossum Pescatorei* album.
To Mr. W. Bull, for *Cypripedium insigne* aurum.
To Mr. W. Bull, for *Alsophia Rebecca*.
To Mr. W. Bull, for *Dracena fragrans* variegata.
To Messrs. Veitch & Sons, for *Phalenopsis Stuartiana*, and *P. Stuartiana nobilis*.

Floricultural Certificates.

To Messrs. Veitch & Sons, for Hyacinth Charles Deon.
To Messrs. Veitch & Sons, for Hyacinth Surprise.
To Messrs. Veitch & Sons, for Hyacinth Delicata.
To Messrs. Veitch & Sons, for Hyacinth Duke of Albany.
To Messrs. Veitch & Sons, for Hyacinth Challenger.
To Messrs. Veitch & Sons, for Anaryllis The Giant.
To Messrs. Veitch & Sons, for Anaryllis Duke of Albany.
To Messrs. Veitch & Sons, for Anaryllis Indian Chief.
To Mr. B. S. Williams, for Anaryllis Dr. Masters.
To Mr. Henry Little, for Cyclamen White Gem.
To Mr. Henry Little, for Cyclamen Crimson Gem.
To Mr. Henry Little, for Cyclamen Tinted Gem.
To Mr. Henry Little, for Cyclamen Rose Queen.
To Mr. Henry Little, for Cyclamen Louis Little.
To Mr. Henry Little, for Cyclamen Strain.
To Mr. Henry Little, for *Azalea indica* Madame de Gréve.
To Messrs. Paul & Son, for *Primula acutilis* *Crossii* flore-pleno.
To Mr. J. George, for Abutilon Emperor.
To Mr. J. George, for Abutilon Brilliant.
To Mr. Todman, for Rhododendron Mr. F. Corbet.

Ealing District Gardeners' Society.—Probably the first *hond fide* flower show of the year was the one which took place in the spacious Drill Hall, Ealing, on the 22d inst., in which was organised, not by the local horticultural society, but by the members of the District Gardeners' Society, who stepped in to fill the void that otherwise would have existed. The result was entirely

satisfactory, for not only were subscriptions liberally forthcoming, but a very charming show was arranged, and well attended. The Drill Hall admits of an exceedingly effective arrangement of mixed groups of plants at intervals, and a show, which, by judiciously combining burning long plants of flowers, assist to create singularly bright and pleasing effects. Of groups of this sort a very brilliant one came from Gunnersbury Park, Mr. Roberts sending forced Lilacs, Rhododendrons, Azaleas, Kalmias, Aconites, Hotens, Gloxinas, and Lachenalia's, all properly flowered. These plants, dressed with Ferns and small Palms, made a beautiful display. A very pretty group came from C. N. Peal, Esq., Ealing (Huntly, gr.), in which Tulips and Hyacinths told with good effect. Messrs. Froome & Sons, of Waltham Cross, had a very pretty group, which included overhanging Palms, some high-coloured Crotons, *Dracena Goldiana*, standard Azaleas in rich bloom and various other ornamental plants, prettily edged by *Adiantum gracillimum*. Mr. G. Weedon, florist, Ealing, staged a very large and fine collection, in which Hyacinth Tulips, Hotias, and *Dieltras*, largely predominating. A grand lot of Cyclamens came from Mr. H. B. Smith's Ealing Dean Nursery, and attracted great attention. The Ealing Floral Company sent a superb wedding bouquet, and a handsome mural vase, in which they exhibited a very fine lot of flowers, set in a vase of Maidenhair Fern. In the class for large groups arranged for effect, Mr. Hudson, gr. to H. J. Atkinson, Esq., Gunnersbury House, took first place with an arrangement in his customary tasteful style—a base of flowering plants and small Ferns, and a capital group of *Centurionida odorata*, &c., from out of which came some elegant Palms. The second place was taken by Mr. Bunn, gr. to E. M. Nelson, Esq., Hanger Hill House, whose centre plant was a fine *Centurionida*, supported by *Phlox*, *Hyacinth*, *Delicata*, *Crotons*, *Heaths*, *Deutzias*, and various effectively grouped plants. Mr. Clements, gr. to C. A. Daw, Esq., Castle Hill, Ealing, who added to his group some good Gloximas and *Cinerarias*, was 3d; and Mr. Fountain, gr. to Miss Wood, Hanger Hill, was 4th. In another class of flowers, set in a vase of Maidenhair Fern, Mr. Summons, gr. to James Henry, Esq., Ealing, who had some well-bloomed Roses; and Mr. A. Stone, gr. to W. Mead, Esq., Village Park, Mr. Hudson was the only exhibitor of foliage plants, having some fine Palms, Crotons, and *Pandanus Veitchii*. *Cinerarias* made a very fine display. In Hyacinths, however, Mr. Beesley was very strong, showing both a six and a four in good form, as also getting an extra award for a miscellaneous group of these flowers, Tulips, and *Narcissus*. Mr. Weedon was 4d, with four kinds. Mr. Beesley was 5th, with six kinds, and a large well-bloomed *Polygala Dulcamara* and *Erica grandiflora rubra*. Mr. McPhun came 2d, with a large white Azalea and a fine *Genista*. In hardy plants Mr. R. Deon was 1st, with some rich coloured *Polyanthuses* and other border plants, and also showing a very fine *Hyacinth* class with a very fine *Hyacinth* golden carpet plant, *Spergula pilifera aurea*. Some fine boxes of cut flowers came from Mr. Hudson, Mr. Fountain, and Mr. McPhun, the former also showing some excellent blooms of *Camelias*. In spite of harsh weather the show was largely attended, and entirely fulfilled the expectations of the promoters.

Fulwood Floral and Horticultural. *March 22 and 23.*—As may be supposed, bulbs, particularly Hyacinths, were the principal feature of the show, over a thousand Hyacinths being staged. In numerous cases the competition was generally very close, the flowers in most cases well developed. *Narcissus* and Tulips were in great force, the flowers collectively being fresh and well timed for the occasion. In the many classes provided for miscellaneous flowering and cut flowers, *Cinerarias*, *Delicatas*, *Aconites*, *Chamaecyparis*, *Primulas*, *Cyclamens*, &c., the competition was strong and close. In almost every class for Hyacinths there were considerably more exhibitors than prizes, with often little to choose between the competing groups. For twenty-four singles, Mr. Troughton, nurseryman, Preston, was well 1st, followed by Mr. Newton, gr. to W. Birley, Esq., a good 2d; Mr. Sharples, gr. to J. B. Dixon, Esq., 3d. Mr. Troughton was likewise 1st with twenty-four doubles, and Mr. Newton 2d, Mr. McDuff, gr. to J. Harding, Esq., being 3d. The Society offered a well-handled *Gold Medal* with money prizes in addition, for twenty-four Hyacinths, twelve double and twelve single; here Mr. Newton took 1st with an even lot of flowers; 2d, Mr. McDuff; 3d, Mr. Rigg, gr. to J. Forshaw, Esq. The Silver Cups offered by Mr. Troughton for the twelve single Hyacinths were both handsomely won by Mr. McDuff, Mr. Newton and Mr. Sharples taking 2d and 3d for singles—Mr. Atherton and Mr. Dewhurst, gr. to E. Birley, Esq., occupying the same positions respectively with the doubles.

For a collection of twenty miscellaneous bulbs in flower a Silver Cup was given by Mr. S. Lyon, Preston, supplemented by money prizes offered by Messrs. Webb, of Stourbridge, and the Society. These brought out a number of competitors, Mr. Gould taking the lead with a nice lot, consisting of Anaryllis, Hyacinths, Nar-

cessus, Tulips, Cyclamens, Gloxinas, &c.; 2d, Mr. McDuff; Mr. Newton 3d. Of twenty miscellaneous plants there were three creditable collections, Mr. Troughton taking 1st with an effective group, in which was a nice *Camassia* *floribunda*, given by Mr. Gould, at the early season in which this variety can be had in bloom—Azaleas, Palms, *Dracenas*, *Aralias*, and a good specimen of *Polystichum*. Six miscellaneous flowering plants: These were nicely shown by Mr. Rigg, who, amongst others, had a good example of *Fraxinus germanica* *jasminoides*, *Croton palmellus*, *Eucharis amazonica*, and *Cero-dendron Balfourianum*. Azaleas were nicely flowered, and large enough to make them effective. For six Mr. Hargreaves took the lead with an even half dozen; Mr. Newton 2d, Mr. Dewhurst 3d. Ferns were well done, Mr. Hargreaves taking the lead with three, the best of which were a well managed example of *Gleichenia rupestris* and *Adiantum tenerum*.

Foliage plants were large and in good condition; for three Mr. Hargreaves had 1st, showing in an even group a very large specimen of *Pandanus Veitchii*. That best of hardy shrubs for forcing, *Deutzia gracilis*, was here shown in a way that we have not seen it elsewhere, taking size and condition into account; Mr. Hargreaves took 1st with three plants, from 4 to 4½ feet through, densely furnished with flowers, and with healthy foliage and a mass of white bloom. *Hetera japonica*, in beautiful condition, were shown by Messrs. Gould, Newton, and Atherton, who took the prizes in the order of their names. *Dicentra spectabilis*, which when well managed in forcing so as to retain the true colour of the flowers, and a stout compact condition in the plants, is not surpassed in elegance by even the most prized occupants of the stove or greenhouse, was well done; Mr. Dewhurst being 1st, with medium-sized specimens; Mr. Newton 2d. Cyclamens were nicely managed, as also were *Cinerarias*.

The above are only a few of the eighty odd classes, of which the schedule is composed, and which collectively made a very attractive and interesting display. Mr. Troughton exhibited, not for competition, a varied and extensive group of plants numbering about four hundred, to which the Gold Medal of the Society was deservedly awarded. Mr. Hoym, of Preston, was also awarded a Silver Medal for a smaller but nice group, similar in character to the foregoing one.

Florists' Flowers.

HYACINTHS AT SOUTH KENSINGTON.—That these were shown in great numbers on the 25th ult. no one could deny; but they scarcely came up to their general average quality was the universal opinion. Yet, it would not have been difficult to select from Messrs. Veitch & Son's large group of over 200 plants an almost matchless twenty-four; as some of the spikes were surprisingly fine. Messrs. Osborn & Son and Messrs. W. Cutbush & Son also had excellent groups, but in point of numbers and quality they fell behind those from the Chelsea Nurseries.

Some fifty plants in Messrs. Veitch's group were new varieties. Of these the Floral Committee selected four for first-class Certificates of Merit, viz., *Delicata*, S. Red, creamy-white, with a pale brown-buff stripe along each segment; the bells large and well-formed, and the spike full and symmetrical. This is a very novel, but a cold and unattractive looking variety, and yet the committee could not have passed it over. It is one of those varieties that may be regarded as intermediate between white and red. *Enchantress*, S.B., is a very pretty and distinct variety, a kind of pale Lord Palmerston, but of a very pleasing mauve-lilac colour, with a white centre to the bells, very pleasing and attractive, forming a good and handsome spike. *Lily, D.R.*, is a double variety, the broad segments slightly striped with pale pink on a creamy-white ground; good compact truss, and quite distinct in character. *Challenger*, S.B., belongs to the claret class, the segments being of a bright claret colour, with a dark stripe along each; they also take on a shining aspect, which imparts to the flower an attractive appearance; very fine spike, and quite distinct.

Other new varieties of a promising character are *Magnificent*, D.B., a greatly improved *Van Speyk*, having large blue bells of fine shape, but wanting greater solidity in the spike, which will probably come with cultivation. *Progress*, S.B., rich deep-shaded violet, full and symmetrical spike; a distinct and pleasing variety. *Supreme*, S.B., pale violet with dark stripes, somewhat dull-looking, but novel in character. *Duke of Albany, D.R.*, a lively-looking double variety of a pale yet bright red colour; distinct, and fine spike. *Mr. Stanley, S.R.*, bright deep red, of a letter blue of colour than King of the Reds; the close spike, extra line. *Clara, S.K.*, a single form of Duke of Albany, bright and effective; good close spike. *Diadem, S.R.*, salmon-red, distinct in

colour, but small in the spike. Orange Boven, S.V., pale yellow, the segments striped with bright reddish-pink; distinct in character, but wants compactness of spike. Charles Dickens, D.L.G., a sport from the single variety, of which it is a double counterpart. Purity, S.W., like Mont Blanc, but with larger and stouter bells; good spike. Marguerite, S.W., large single white; good spike. Saifano, S.V., pale citron-yellow; good spike. Cinoline, S.R.K., bluish-pink, with slight rose-pink stripes; large bells and good spike. Sparkler, S.B., deep violet-blue, with white centre; bells small, but very pretty. Sunrise, S.R.K., bright red, in the way of Vuurbaak, close spike; an effective variety.

Looking over Messrs. Veitch & Son's group, a selection of the best varieties would include, of D. black, General Havelock, Mimosa, very fine spike; Duke of Connaught, very fine deep shining blackish-purple, striking colour; and Masterpiece, glistening purple-black, very fine. Deep blue: Thiers, the deep violet-blue segments margined with pale greyish-blue; Marie, in the same way, but better; King of the Blues, very fine; and Baron Von Tuyl. Pale blue: Electra, very fine; Grande Bleu, very fine; Lord Derby, really splendid in development; Grande Maitre, extra fine, the close symmetrical spike of great length; Princess Mary of Cambridge, very fine spike; Czar Peter, very pretty and pleasing; Charles Dickens, very fine; Lothair, Triple Crown, pale violet-blue, very fine and distinct; and Blondin. These pale blue single Hyacinths make a very fine group indeed. Deep red: Pelissier, Reine des Hyacinthes, Prima Donna, Linnaeus, Lina, Von Schiller, King of the Reds, Garibaldi, and Vuurbaak, a very fine lot indeed. Pale red: Koh-in-noor, Macaulay, Lady Palmerston, a very pleasing variety; Etna, very distinct and fine; Princess Helena, pretty pale pink; Princess Louise, pale bright rose, very pretty; Ornement de la Nature, Fabiola, and Lady Bountiful, very pretty pale pink. Yellow: King of the Yellows, a variety of such a fine hue of colour and so good in every respect that it will be a long time ere it is improved upon; Grand Duc de Luxembourg; Marchioness of Lorne, pale buff, very distinct, fine spike; Obelisk, pale yellow, fine spike; Ida, and Bird of Paradise, white; Snowball, Ornement, Rose, bluish-white; La Grandesse, Purity, Miss Nightingale, Lord Shaftesbury, very large bells; Marie Stuart, Baroness Von Tuyl, Madame Van der Hoop, Grandeur à Merveille, and l'Innocence.

Messrs. Osborn & Son's fine group, though not so extensive as Messrs. Veitch's, contained some spikes well worthy of notice. Of blue varieties, the most striking were General Vander Heyden, pale lavender with azure-blue striping along the segments—large close spike; Lothair, very good; Argus, fine in colour; Charles Dickens, with a rare depth of colour; Triple Crown, very fine bells and compact spike; Cavalcade, very large bells and broad segments, margined with azure-blue on a greyish-lavender ground, the points of the segments of a deeper blue—very fine; Grand Bleu, very fine; and Czar Peter, very fine. Red Beauty of Waltham, small bells and narrow segments, but with a peculiarly pleasing deep hue of pink, pale centre, good spike; Charles Dickens, pale red; Von Schiller, very fine; Princess Louise, double, pale rose, the segments tipped with green, distinct, fine spike; Princess Helena, very bright pale pink, good bells and spike, distinct; Solitaire, very rich in colour; Prima Donna, very bright red; Linnaeus, very fine; Vuurbaak. White: La Grandesse, Snowball, very fine; Lady Derby, pure white, very good bells; and Snowspike, in the way of Lady Derby. Yellow: Grand Duc de Luxembourg, l'Or d'Australie fine deep yellow; King of the Yellows and Jonquillon, a good hue of yellow, fine spike and bells.

In Messrs. Cutbush & Son's group the following were the leading varieties:—Grandeur à Merveille, very fine indeed, and so greatly in advance of this variety in other groups as to have the appearance of a distinct strain; Lady Derby, Mont Blanc, King of the Blues, Charles Dickens, very fine; Lord Derby, Blondin, Lord Palmerston, very fine in colour; Duke of Connaught, very fine; Macaulay, Garibaldi, very fine in colour; Sir William Mansfield, pale claret, with deep broad stripes along the segments; Princess Clotilde, pretty bright pinkish-rose; Bird of Paradise, and Ida.

Some of the early flowering Tulips shown on this occasion deserves a passing notice. The best flowers were in Messrs. Cutbush & Son's group, and consisted of Yellow Pottebakker, Prosepine, Vander Neer,

purple; Joost Van Vondel, fine rosy-crimson; Rose Louisante, White Pottebakker, Cerise Gris de Lin, a charming variety, the cerise-red petals being broadly tipped with white; Roi Perin, a charming striped variety; and the old double Tournesol. In Messrs. Osborn & Son's group was a very pretty rose-coloured self of fine shape, named Adeline, like a rose-coloured form of Prosepine; Bird of Paradise, a very fine golden-yellow self, with a greater depth of colour than is found in Chrysolora; the white form of Joost Van Vondel, which sometimes comes prettily striped with white on a crimson ground; Vermilion Brilliant, fine in colour; and Queen of Vellies, soft pale violet. R. D.

with its bull placed on grass and fully exposed to the sky was 23° 50, on the 20th; the mean of the seven readings was 31° 4.

Rain fell on five days to the amount of 0.45 inch.

ENGLAND: Temperature.—During the week ending March 25 the highest temperatures were 65° 4 at Cambridge, 64° at Sunderland and 63° 6 at Nottingham. The highest temperature at Brighton was 53° 3, at Hull 55°, and at Bolton 55° 1. The general mean was 59° 2.

The lowest temperatures in the week were 25° 2 at Nottingham, 26° 3 at Wolverhampton, and 27° 5 at Leicester. The lowest temperature at Truro was 35°, at Plymouth and Liverpool 33° 5. The general mean was 30° 2.

The greatest ranges of temperature in the week were 38° 4 at Nottingham, 36° 4 at Cambridge, and 34° 9 at Wolverhampton. The least ranges were 23° 8 at Liverpool, 24° 3 at Plymouth, and 24° 5 at Bristol. The general mean was 29°.

The mean of the seven high day temperatures was highest at Cambridge, 56° 1, at Sunderland 55° 4, and at Truro 54° 3; and was lowest at Bolton, 47° 2, at Hull 48° 7, and at Liverpool 49° 4. The general mean was 51° 9.

The mean of the seven low night temperatures was highest at Truro, 42° 9, at Plymouth and Liverpool 39°; and lowest at Nottingham, 33° 4, at Wolverhampton 33° 6, and at Hull 34° 3. The general mean was 36° 7.

The mean daily range was greatest at Cambridge, 26° 3, at Nottingham 19° 8, and at Blackheath 17° 6; and was least at Liverpool, 10° 4, at Truro 11° 4, and at Bolton 11° 7. The general mean was 15° 2.

The mean temperature for the week was highest at Truro, 47° 5, at Sunderland 45° 6, and at Plymouth 45° 2; and was lowest at Bolton, 40° 3, and at Wolverhampton and Hull, 41° 5. The general mean was 43° 2.

Rain.—The largest falls were 2.05 inches at Bolton, 1.34 inch at Bradford, and 1.30 inch at Liverpool. The smallest falls were 0.17 inch at Plymouth, 0.23 inch at Bristol, and 0.29 inch at Sunderland. The general mean was 0.81 inch; it fell on an average of five days.

SCOTLAND: Temperature.—During the week ending March 25 the highest temperature was 56°, at Paisley; at Greenock the highest temperature reached in the week was 51°. The general mean was 53° 4.

The lowest temperature in the week was 29°, at Greenock; at Leith the lowest temperature was 34°. The general mean was 30° 8.

The mean temperature for the week was highest at Paisley, 44° 5; and at Leith 44° 4. The general mean was 42° 7.

Rain.—The largest fall was 1.50 inch, at Greenock; the smallest was 0.29 inch, at Dundee. The general mean was 0.92 inch.

JAMES GLAISHER, F.R.S.

Enquiries.

He that questeth much shall learn much.—BALCON.

PEAT MANURE.—Have any of our readers any experience to offer on the value of moss-peat manure? The peat is used as a substitute for straw in London stables, and it absorbs about five times its weight of liquid.

POLLEN OF DATE PALM.—The Curator, Botanic Garden, Cambridge, would be grateful to any English or foreign correspondent for a supply of fresh pollen of the above in a glass tube or quill.

Answers to Correspondents.

* We shall be much obliged if our correspondents will favour us with their communications a day earlier next week.

BEANS: J. W. S. The weevil is the well-known Bruchus granarius. The beans will grow in all cases where the weevil has not eaten through the germ but only through the seed-lobes.

CAPTUSES NOT BLOOMING: J. O. H. Expose them freely to sun-heat, and when growing feed them with liquid manure. Most people starve them too much.

CINERARIAS: J. Richards. Your flower is only semi-double and of no value as it is, but you might save seed from it with a view to improvement.—J. Kingdon. A very good double flower, almost, if not quite, identical with a variety Mr. Vertegans grows under the name of Vertigera.

GIGEA TRITRERA: H. J. Ross. Cedra tritpera, Don, is the same as C. Baueriana, Lindl., and the original name was Cymbidium tritperum, Swartz. It is a native of the West Indies and Mexico. W. B. H.

DAPHNES: E. Webster. Daphne Biegiana is scarce yet, but we should suppose that any of the leading nurserymen could supply you with the others, or procure them for you.

GREENHOUSES RATEABLE: T. Barry. Yes.

HIBISCUS SINENSIS: J. H. The largest, and in some respects the finest double-flowered variety of H.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, MARCH 29, 1882.

Table with columns: MONTH AND DAY, BAROMETER, TEMPERATURE OF THE AIR, Hygrometrical Deductions, WIND, RAINFALL. Rows for Mar 23-29 and a Mean row.

Mar. 23.—A fine day, generally overcast. Dark cloudy night. Wind clear and cloudy alternately. Strong wind. 24.—A fine day, sun shining at intervals, cloudy and clear alternately. A wet night. 25.—A fine day, sky overcast. Fine night. 26.—A fine day, overcast. Fine night, clear and cloudy alternately.

LONDON: Atmospheric Pressure.—During the week ending March 25, the reading of the barometer at the level of the sea decreased from 30.20 inches at the beginning of the week to 30 inches by 3 P.M. on the 19th, increased to 30.01 inches by midnight of the same day, decreased to 29.77 inches by 3 P.M. on the 20th, increased to 29.84 inches by midnight of the same day, decreased to 29.72 inches by midnight of the 21st, increased to 29.77 inches by midnight of the 24th, and was 29.37 inches at the end of the week.

The mean reading for the week at the level of the sea was 29.88 inches, being 0.62 inch lower than last week, and 0.1 inch below the average of the week.

Temperature.—The highest temperature in the shade in the week was 62° 5, on the 20th. The highest temperature on the 22d was 43° 8. The mean of the seven high day temperatures was 53° 8.

The lowest temperature in the shade in the week was 30°, on the 23d; and on the 24th the lowest temperature was 44°. The mean of the seven lowest temperatures was 36° 2.

The greatest range of temperature in one day was 25° 5, on the 20th; the smallest was 10°, on the 24th. The mean of the seven daily ranges was 17° 6.

The mean temperatures were, on the 19th, 45° 0; on the 20th, 49° 7; on the 21st, 45° 9; on the 22d, 36° 2; on the 23d, 40° 4; on the 24th, 48° 3; and on the 25th, 45° 9. Of these those of the 19th, 20th, 24th, and 25th were 6° 9, 8° 0, 6° 2 and 3° 0 respectively above their averages, those of the 21st, 22d, and 23d were 0° 9, 5° 7, and 1° 6 respectively below the averages.

The mean temperature of the air for the week was 44° 4, being 3° 1 lower than last week, and 2° 4 above the average of the week.

The highest reading of a thermometer with blackened bulb in vacuo, placed in the full rays of the sun, was 122° on the 19th; the highest on the 24th was 68°. The mean of the seven readings was 104°.

The lowest reading of a minimum thermometer

sinensis we have ever seen ; colour, rosy-scarlet. It is well worth perpetuating and sending out under a distinctive garden name. Could you oblige us with a flower not quite so fully developed?

IVY: R. Best. Clip off the whole of the leaves and burn them before the ivy commences to grow again.

LABELS: J. Jacobs. Write for particulars to the Secretary of the Society of Arts, John Street, Adelphi, W.C.

MALFORMED ONCHIDIUM: A. Probably the result of a fusion of three flowers, as there are three columns. There are, however, only seven perianth-segments and two lips, so that several parts have been suppressed. It is singular that on the same plant the leaves should show a tendency to be united back to back, like the letter X.

NAMES OF PLANTS: Simon. 1. Cypridium barbatum-biflorum; 2. Lycaste Harrisoniæ.—Evelyn-Boad. Alonsoa linearis, alba Celsia linearis, or a very spindly growth of A. incisifolia. The Fern is Lastrea emula.—M. didima. We believe they are—1. Dendrobium aggregatum; 2. Dendrobium Pierardi katiifolium; 3. but you should have sent more particulars.—P. J. Forsythia suspensa.—R. H. P. So far as we can tell from your description and the leafless scrap you send, the Laurustinus is the variety known in the nurseries as lucida.—E. A. E. 1. Dieris, 2. Hardsenbergia Comptoniana; 3. Cotonaster boxifolia; 4. we cannot name without flowers; 5. Alternanthera achanthata; 6. Amarantus chlorostachys.—J. H. H. We are unable to name your plants without flowers. No. 1 appears to be a species of Calceia; 4 is a Calceola; and 5 is one of the numerous varieties of Codium variegatum.—C. H. Lathraea squarrosa.

PROPAGATOR: F. Palmer. We think it would be useless to advertise. Your best plan would be to go out to New York or Melbourne, and put yourself in communication with the horticulturists there.

QUEEN'S TAXES: R. J. K. You must pay the tax.

ROOT-PRUNING PEAR TREES: I. O. W. The end of September or the month of October is the best time for doing this. We should think your trees do not want root-pruning; they more probably want manure.

SALIX BABORDIANA: Cor. Herford Messrs. Rodger, McClelland & Co., of Newry, can supply this Willow.

SEAKALE AND ASPARAGUS BEDS: I. O. W. Apply the salt now, before growth commences. Nitrate of soda applied to the Asparagus at the rate of 2 lb. per square yard will give you much better results. Transplant in spring, also before growth commences.

SEEDS FROM PHILIPPINE ISLANDS: L. M. G. The "Nipas" are, we should suppose, the seeds of a Palm-like plant, Nipa frutescens, common in the sundarbans. The genus Baubinia is mostly composed of Leguminous slow climbing plants common in the tropics. Cissampelos is the name of a genus of Leguminous dwarf trees, or large shrubs, also natives of tropical climes. C. sappan forms a tree in the East Indies, and furnishes the Sappan wood of commerce.

VINES: C. H. They have had a check in some way, inducing a tendency to proliferation in the leaves, but will grow out of this state with genial weather.—G. H. We think the shrivelling is due to withering while the leaves have been wet.

WEEDS: John Colebrooke. Foul 1 lb. of arsenic in a gallon of water for half-an-hour, then add from 4 to 5 galls. of cold water, and pour it on the walks carefully. One dressing a-year will suffice, but the mixture must be used with the greatest caution.

* Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editor," and not to any member of the staff personally. The Editor would also be obliged by such communications being written on one side only of the paper and sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Letters relating to ADVERTISEMENTS, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editor.

Markets.

COVENT GARDEN, March 30.

The present fine weather is driving a lot of forced stuff into our market, and with the holidays before us we must expect low prices. The largest cargo of St. Michael's Pines reached us this week in fine condition, nearly 5000 being sold in one day. James Webber, Wholesale Apple Market.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table with columns for fruit types (Apples, Grapes, Kent Cobs, Strawberries) and prices per bushel or per lb.

VEGETABLES.—AVERAGE RETAIL PRICES.

Table with columns for vegetable types (Artichokes, Asparagus, Jersey, Spruce, Barbe de Capucio, Beans, Cauliflowers, Celery, Celeriac, Cucumbers, Endive, Garlic, Keut Regents, etc.) and prices per doz. or per lb.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

Table with columns for plant types (Aralia Sieboldii, Arbutus-vitæ, Begonia, etc.) and prices per dozen.

CUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table with columns for flower types (Abutilon, Arum Lilies, Azalea, Bouvardias, Carnielis, etc.) and prices per bunch or per dozen.

SEEDS.

LONDON: March 29.—The seed market has lately been well attended, and a good business doing. Stocks of all descriptions of seeds are now in narrow compass, and prices consequently show great firmness. Canadian Clover seed, being remarkably clean, meets with increasing favour. Of fine new English red, the supply seems almost exhausted. Alsike, white, 12s. 6d.; Hutton reduce full rates. For spring Tares there is less inquiry. The sale for bird seeds is slow. Feeding Linseed unchanged. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

POTATOS.

The Borough and Spitalfields Markets reports state that supplies of both home-grown and foreign are moderate, and the trade quiet, with very little change in prices. Quotations.—Flukes, 120s. to 140s.; Victor, 100s. to 110s.; Scotch Champions, 60s. to 70s.; ditto King's, 60s. to 70s. per ton. German Reds, 3s. 6d. per bag.—The imports into London last week comprised 400 bags and 88 sacks from Bremen, 600 bags Hamburg, 114 bags Cadix, 20 sacks Algiers, 54 bags Harlingen, and 58 tons from Roscoff.

COALS.

The following are the prices current at market during the week:—Ravenworth West Hartley 13s. 6d.; East Wylam, 15s.; Walls End—Hutton, 12s. 6d.; Hutton Lyons, 13s.; Hawthorns, 13s. 3d.; Lambton, 14s.; Hutton Hartlepool, 14s. 6d.; Wear, 13s.; South Hetton, 14s. 6d.; Chilton Tees, 13s. 6d.; Tees, 14s. 3d.; Thornley, 14s. 3d.

CATALOGUE of the above may be had Post free upon application.
THOMAS S. WARE,
HALE FARM NURSERIES, TOTTENHAM, LONDON.

AQUILEGIAS (Seeds). Few have the slightest idea of the beauty, elegance, and the use of this splendid hardy plant, and to be quite sure that our seed shall be the best, we purchased the stock of two most noted raisers of new kinds—viz., Messrs. Douglas and Cruikshank, and we have great pleasure in offering it to our friends in 12, and 25 packets, mixed, from all the best named in cultivation. Here, again, to be quite sure that our Gloxinia seed is the best, and if possible to improve on our stock, we purchased at a high price the seed which the *Gardeners' Chronicle* alludes to in the following eulogistic terms:—

Gloxinias Exhibited at the Richmond Show and Royal Botanic Gardens, Regent's Park.—"It is a goodly group of the most beautiful summer decorative flower should evoke special praise from some of our oldest plant judges indicates that they were unusually good." We doubt whether finer plants, more superbly flowered, were ever put upon a show table. The blooms were not only large, but of rich colours, and the finest quality. These plants exhibit what can be done towards making the Gloxinia a summer exhibition plant and it must be admitted that in beauty and richness it stands second to none other. Since the Gloxinia has been taken in hand by the florists, it has developed grand qualities and such brilliant hues as to put many flowers in the shade."

Mixed Seeds, 2s. 6d. per packet.

H. CANNELL & SONS,

New Catalogue of Seeds and Plants FOR 1882.

How to Destroy Weeds, Moss, &c., on Gravel Walks.—Use

SMITH'S celebrated **WEED KILLER**, the most successful thing of the day. It is a liquid preparation, which when mixed with cold water, and applied with an ordinary watering-can, proves thoroughly destructive to all vegetable growth. For particulars and a list of first-class Testimonials, address to the manufacturer,
MARK SMITH, Chemist, Louth, Lincolnshire.

The **WEED KILLER** is sent carriage paid to any Station in England or Scotland.

GISHURST COMPOUND.—Used by many of the leading Gardeners, since 1820, against Red-spider, Mildew, Thrips, Greenfly, and other blights. Its solutions of from 1 to 2 oz. to the gallon of soft water, and of from 4 to 10 oz. as a winter dressing for Vines and Fruit Trees. Has outwitted many preparations intended to supersede it. In Boxes, 12s. 3s., and 10s. 6d.

AMERICAN BLIGHT ON APPLE TREES CURED by rubbing a wet hard Painter's brush on Gishurst Compound, and working the latter into the infected part.

GISHURSTINE keeps feet dry, softens hard boots, preserves leather, takes a polish. In boxes, 12d. and 1s. each.

Wholesale by **PRICE'S PATENT CANDLE COMPANY (Limited)** Retail by Seedsmen and Oilmen.

Medicated Tobacco paper improved and only genuine make. The most effective and safest fumigator should be used with the improved fumigating Pan. Used Circulars and all particulars post free.

Oil Paint no Longer Necessary.
HILL AND SMITH'S BLACK VARNISH,
for Preserving Ironwork, Wood, or Stone.
(Registered Trade Mark)

This VARNISH is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received.
Sold in Casks of about 35 gallons each, at 12. 6d. per gallon at the Manufactory, or 12. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL.
"Stonfield Park, June 21, 1876.—Sirs.—I have this day forwarded from Chestnut to your address a black varnish cask, to be filled and returned with its good varnish, at the rate last we had, which I candidly admit was the best we ever had. Address Varnish to Chestnut Park, Chestnut.—I am, Sirs, yours respectfully, Wm Cox."

CAUTION.—HILL & SMITH would particularly warn their Customers against the various cheap Varnishes now so much advertised.
H & S's Varnish has been an article of common use on most of the large estates in the kingdom for upwards of thirty years; and their constantly increasing trade in it, and the numerous Testimonials they receive, stamp it as a truly genuine article. Every cask is legibly marked with their name and Registered Trade mark as above, without which none is genuine.
Large Illustrated CATALOGUE of Fencing, Hurdles, Field and Entrance Gates, &c., sent free on application to
HILL AND SMITH, Inverley Hill Ironworks, Staffordshire;
18, Queen Victoria Street, London, E.C.; and 130, Buchanan Street, Glasgow.

COMPLETE PRICE LISTS FREE BY POST.

STOCK KEPT IN LONDON at Arch 92, Spitalfields Station, Bethnal Green, E., and Machines may be ordered from any respectable ironmonger.

Ransomes, Head & Jefferies, ORWELL WORKS, IPSWICH.

THE "WORLD"

THE "AUTOMATONS" have front rollers for general work, and side rollers for cutting long grass, or when it is unnecessary to roll the grass in front of the cutters. They have the best machine made gear, and the best self-sharpening knives of steel and iron rolled together, and automatic silent drivers.

R. H. & J. also manufacture "REVERSIBLE" Lawn Mowers for Small Gardens and Borders, and "HORSE-POWER" Lawn Mowers for Large Lawns, &c.

The "WORLD" (late "GLOBE") Lawn Mowers are intended for cutting long grass; and, whilst similar to the Lawn Mowers imported from America, have the special advantages of the more accurate fitting and general durability of English manufacture and perfect adjustment.

The "WORLDS" will cut wet, dry, long, or short grass without clogging, and cut off almost all the "beats." They leave the surface smoother than similar machines, and are well adapted for getting over a large amount of work with little labour.

MELBOURNE EXHIBITION, 1881. THE HIGHEST AWARD.

SEE THE NEW
AMERICAN LAWN MOWERS,

GARDENER (HEAD).—No family. Thorough practical and energetic man, well up in every branch of the profession. Stove, Greenhouse, Conservatory, Fruit and Potted Plants, and all the various branches of the highest class. Land and Stock if required.—HORTUS, 43, Alfred Street, Spald Brook, near Birmingham.

GREEN'S PATENT "SILENS MESSOR" AND OTHER LAWN-MOWING, ROLLING and COLLECTING MACHINES for 1882.

THE WINNERS OF EVERY PRIZE IN ALL CASES OF COMPETITION.

Patronised by Her Most Gracious Majesty the Queen on many occasions, His Royal Highness the Prince of Wales, the King of the Belgians, the late Emperor of the French, the Emperor of Russia, and most of the Nobility, Clergy, and Gentry of the United Kingdom.

Royal Horticultural Society's Show, South Kensington, London, June 3 to 7, 1881. The "Journal of Horticulture," of June 7, 1881.—"Mowing Machines.—After a critical examination the Silver Medal was granted to the old firm of world-wide fame, Messrs. T. Green & Son, of Leeds and London. As the machines are known in all lands where good lawns are cherished, it is quite unnecessary to give any description of them."

Upwards of 105,000 of these Machines have been Sold since they were first introduced in the year 1856, And Thousands of unsolicited Testimonials have been received testifying to their superiority over all others.

They have been submitted to numerous practical tests in Public Competition, and in all cases have carried off every Prize that has been given.

The following are their advantages over all others:—

- 1st. Simplicity of Construction—every part being easily accessible.
- 2d. They are worked with much greater ease than any other.
- 3d. They are the least liable to get out of order.
- 4th. They make little or no noise in working.
- 5th. They will cut either short or long Grass, wet or dry.

Single-handed Lawn Mower.

To cut 6 inches	Price £1 15 0
Can be worked by a Lady.	
To cut 8 inches	2 10 0
Can be worked by a Lady.	
To cut 10 inches	3 10 0
Can be worked by a strong Youth.	
To cut 12 inches	4 10 0
Can be worked by a Man.	
To cut 14 inches	5 10 0
Can be worked by a Man.	

Double-handed Lawn Mower.

To cut 16 inches	Price £6 10 0
This can be worked by One Man on an even lawn.	
To cut 18 inches	7 10 0
By a Man and Boy.	
To cut 20 inches	8 0 0
By a Man and Boy.	
*To cut 22 inches. By Two Men ...	8 10 0
*To cut 24 inches. By Two Men ...	9 0 0
* It made stronger, suitable for Donkey, 30s. extra.	

Prices of Donkey, Pony, and Horse Machines, including Patent Self or Side Delivery Box, with Cross-stay complete, suitable for attaching to Ordinary Chaise Traces or Gig Harness:—

DONKEY and PONY MACHINES.

To cut 26 inches	£14 0 0
To cut 28 inches	16 0 0
To cut 30 inches	18 0 0
Leather Boots for Donkey	1 0 0
Leather Boots for Pony	1 4 0

HORSE MACHINES.

To cut 30 inches	£22 0 0
To cut 36 inches	26 0 0
To cut 42 inches	30 0 0
To cut 48 inches	34 0 0
Leather Boots for Horse	1 9 0

The 26 and 28 inches can easily be worked by a Donkey, the 30 inches by a Pony, and the larger sizes by a Horse; and as the Machines make little noise in working, the most spirited animal can be employed without fear of its running away, or in any way damaging the Machine.

GREEN'S PATENT "MULTUM IN PARVO" LAWN MOWER.

PRICES.

Without Grassbox.

To cut 6 in. £1 1 0
To cut 7 in. 1 8 0
To cut 8 in. 1 15 0

This Mower is specially designed to meet an almost universal want experienced by those who have small lawns or grass plots, to have a good and useful machine at a low price. The inventor having seen this want continually increasing, year by year, has brought out the Mower to meet the requirements of the public by supplying a good and useful machine at a cheap rate.

It is simple in construction, easily adjusted, is well adapted for mowing small plots, cutting borders, verges, round flower beds, the edges of walks, &c.; it is a most handy, servicable machine, and very easy to work.

PRICES.

With Grassbox.

To cut 6 in. £1 5 0
To cut 7 in. 1 13 0
To cut 8 in. 2 0 0

GREEN'S PATENT GRASS EDGE CLIPPER.

Specially designed to cut the overhanging grass on the edges of walks, borders, flower beds, &c., and to do away with the tedious operation of cutting with shears.

SIZE and PRICE.

Wide. ..	Diam. ..
8 inch ..	7 inch ..
Packing Case, 2s.	

GREEN'S PATENT LAWN TENNIS COURT MARKER.

This Machine is of novel design and construction, and the simplest and most effective in its operations.

In the trough containing the liquid there is a loose drum which revolves when the machine is in motion, and conveys the marking material to the intermediate pulley, which in its turn transmits it to the front one, so that the ground is marked effectively as the machine is pushed along.

Price, 21s.

Small Bag of Patent Marking Composition, Mat, and Packing, 1s. 6d.

Delivered, Carriage Free, at all the principal Railway Stations and Shipping Ports in England, Scotland, and Ireland.

No Lawn Mower Manufacturer keeps so large a stock of Mowers as is to be found at our London Establishment, 54 and 55, Blackfriars Road, where purchasers can select out of several hundred Machines, of Hand, Pony, and Horse Power, and have their Orders executed the same day they are received.

The above Machines are Warranted to give entire Satisfaction, otherwise they may be returned AT ONCE, free of cost to the Purchaser.

N.B.—Those who have Lawn Mowers which require repairing should send them to either our Leeds or London Establishment, where they will have prompt attention, as an Efficient Staff of Workmen is kept at both places.

Garden Seats and Chairs, and Horticultural Implements of every description, Wire Netting, &c., &c.

Descriptive Illustrated Price Lists free on application to

THOMAS GREEN & SON (Limited), Smithfield Ironworks, Leeds; and 54 and 55, Blackfriars Road, London.

GRASS SEEDS

FOR LAWNS,
Of the finest close-growing Evergreen kinds, 1s. per lb. Special preparations for all purposes, soils, and situations. Advice gratis.

Unsolicited Testimonials:—
"Knowing how difficult it is to obtain pure stocks of grass seeds, even when price is a secondary consideration, I wish to say the supply I obtained from you for our new terrace lawns has given the greatest satisfaction."
"Please send me three bushels of the very best Lawn Grass seeds, suitable for an excellent high and level lawn. The seed I have had of you has been the only kind which has been able to resist the influence of the sun and drought upon my lawn, gravely soil."

FARM SEEDS

Of all kinds, which have given unequalled satisfaction. See Illustrated and Descriptive LIST, free on application.

(ESTABLISHED 1804.)

NOTICE.
SELLING OFF OF NURSERY STOCK.

EWING & CO.,

EATON, near NORWICH.

Great Reduction in Price for Cash Payments, viz.:
15 per Cent. for Cash before delivery.
10 per Cent. for Cash within One Month of date of invoice.
5 per Cent. for Cash within Three Months of date of invoice.
After Three Months no discount can be allowed.

PRICE LIST OF THE FOLLOWING

is now preparing, and will be forwarded gratis and post-free to applicants:—

New and Scarce ROSES, Tea and Noisette ROSES; CLEMATISES, of best New and Old Varieties; Variegated and Choice Green-leaved IVIES, and other Hardy CLIMBING and CREEPING PLANTS; JAPANESE and other Choice PRIVETS, EUONYMUS, AUCUBAS, HYDRANGEAS, &c., all in pots.

N. B. Cut Roses, &c., can be supplied at cheap rates, carefully packed for travelling long distances.

A slight extra charge must in most cases be made for packing. Where cash in payment of goods is sent with the order, the amount for postage may be forwarded in stamps after despatch of goods.

N. B. Post-office Orders should be made payable to EWING AND CO., at Eaton, near Norwich. Cheques crossed GURNEY AND CO., Norwich.

Trade Terms on application.

WHITE ELEPHANT POTATO.

THE MOST WONDERFUL CROPPING POTATO IN THE WORLD.

For this splendid Cooking variety we received Certificate of Merit from the Royal Horticultural Society, November 3, 1881.

The True Stock 6d. per pound; 7 lb., 3s.; 14 lb., 6s.; 56 lb. 18s.; 112 lb., 34s.

TESTIMONIALS:

From Mr. E. CLARK, King's Langley, Herts, October 29, 1881.

"From the one pound of WHITE ELEPHANT POTATO I have lifted 206 lb. weight."

From Mr. KERRY, Halton Holgate, Spilby, October 27, 1881.

"The one pound of WHITE ELEPHANT has turned out very fine. I have lifted 226 lb. from it."

DANIELS BROS.,
ROYAL NORFOLK SEED ESTABLISHMENT,
NORWICH.

NATIVE GUANO,

SUITABLE FOR ALL CROPS.

Price, £3 10s. per Ton, in Bags, at Aylesbury.

A single cwt. Sample Bag sent, Carriage Paid, to any Railway Station upon receipt of Post-office Order for 5s.

This valuable Manure, prepared from Sewage by the "A B C" process, has been extensively used, for several years, by Farmers, Gardeners, and others, whose reports testify to its fertilising properties.

EXTRACTS FROM LAST SEASON'S REPORTS:—

WILLIAM CURME, Gr. to Duke of Marlborough, Bienenheim Palace Gardens, December 12, 1881.

"Used for Vines, Peach trees, and other fruit trees, also Potatoes, Carrots, Parsnips, Onions, &c. Results: satisfactory. Fruit trees assumed rich dark green foliage, increased vigour whilst the fruit swelled up to a very fine size. Potatoes come out in splendid condition; other roots too were benefited by its application. No other manure used with Native Guano. Undoubtedly a valuable fertilising agent, and I shall lose no opportunity of recommending it to gardeners and others."

A. BLAKE, Head Gr. to H. Cameron, Esq., The Lilies, Wotton, January 3, 1882.

"Used for Peas, Potatoes, Onions, Cabbage, Cauliflowers, Celery, Vines, Cucumbers, &c.; Chrysanthemums, Primulas, Geraniums, Fuchsias, &c. Result: Onions, Cabbage, Cauliflowers, and Peas good; Cucumbers, first-rate. Potatoes, a good crop, and I consider it a good manure for pot plants. I think the Native Guano only requires to be more known to the public to be largely used."

Sixteen Prizes awarded at Birmingham Show, 1881.

The Annual Show of Farm and Garden Produce, grown with Native Guano, will be held at Aylesbury in October next. Schedules and Prizes and all particulars, together with testimonials, &c., may be obtained upon application to

The Native Guano Company (Limited), Aylesbury, Bucks.

LA BELLE SAUVAGE YARD, LUDGATE HILL, LONDON, E.C.; 21, BACHELORS' WALK, DUBLIN.

Awarded 1st Prize at the Sydney Exhibition, 1880. Awarded 1st Prize at the Melbourne Exhibition, 1881. Also awarded Silver Medal at the Royal Horticultural Society, June, 1881, for collection of Garden Implements, Tools, &c., &c.

"THE COVENTRY."
(REGISTERED).

NETTLEFOLD & SONS desire to call especial attention to their "COVENTRY" LAWN MOWER, which they can confidently recommend as the best and cheapest in the Market.

It has all the improvements which have of late been introduced into this class of Machine, either in England or America; and for the manner in which it does its work, its lightness, and the ease with which it can be used, cannot be surpassed. Its cheapness brings it within the reach of every one, and in this respect it defies competition with any American machine before the public. It is made, as its name implies, at Coventry, by skilled English workmen, and of best English Steel and Iron. These Machines can also be supplied with ROLLERS AT SAME PRICE, and GRASS BOXES at a small extra cost.

THE Gardeners' Chronicle.

SATURDAY, APRIL 8, 1882.

GARDENIAS.

AMONG the many changes and contrasts between the horticultural practice of the present and the past, perhaps there are none more striking and complete than that relating to the culture and position of Gardenias. Only a few years ago very few were grown, and those few were mostly very indifferently cultivated. Seldom were more than from six to a dozen found in private places, and few or none were grown by the trade. The old variety—radicans, single and double—was almost the only sort grown at all, and the plants were not seldom the victims of mealy-bug, thrips, and spider, being as full of insects as of flowers. Here and there the improved *C. florida* might have been met with in better condition, but these were rare exceptions. The plants were looked upon as miffy growers, specially liable to insect pests, and hardly worth growing. A great mystery was made of the art of growing clean, healthy, and floriferous Gardenias, and for many years the art remained in such few hands as to be practically unknown. A glimpse of the truth, however, oozed out occasionally, associated with dung beds for bottom-heat. The introduction of larger-flowered species or varieties, such as *Fortunei*, *intermedia*, &c., also gave a stimulus to *Gardenia* culture. With the prospect of obtaining *Gardenias* as large as small *Camellias*, and sweeter than *Jasmine*, *Rose*, and *Stephanotis* combined, *Gardenia* culture took a fresh departure. Though for a time the progress made was slow, and the highest measure of success may not have been reached as yet, yet the *Gardenias* of to-day are as unlike as the same plants or family could well be to those of a quarter of a century since. And not only have the plants improved almost out of recognition, but their numbers have increased beyond enumeration. For every one grown in gardens five-and-twenty years ago, there are probably a thousand cultivated now. Go where one will, one meets with scores, hundreds, thousands, housefuls of *Gardenias*. Gardens, markets, and shops, are crowded with them. At Easter, especially, no flowers are more popular or more profitable. From 6d. to 2s. 6d. is thought a fair price for a prime *Gardenia*. The *Camellia*, *Rose*, *Carnation*, *Tuberose*, *Stephanotis*, have a hard struggle to hold their own in public favour against or abreast of the new favourite. The purity of its whiteness, the fulness of its fragrance, are unrivalled for wreaths, bouquets, room, table, and church decoration. It is in universal demand and esteem. The decorative value in the stove or main conservatory is also of the highest order—their habit is excellent, their foliage of the deepest glossy green, which sets off their flowers to the best advantage. So fashionable have *Gardenias* become and so substantial are their merits, that it is hardly an exaggeration to add, that they are found in almost every garden, and that the more largely they are cultivated, the more satisfactory and enjoyable the garden. All this being true,

it becomes every day a matter of more practical importance to show how our present success in *Gardenia* culture has been reached: chiefly, through more root-room and higher temperature, and a more liberal allowance of food and water. So greedy is the *Gardenia* of root-room that its perfect culture can hardly be reached in pots, however large the latter may be. The first man that planted out a *Gardenia* was as great a benefactor to his species probably as the historical person who made two blades of grass to grow where one only grew before. It is certain he pointed out the way to grow *Gardenias* to perfection, and was the progenitor of those thriving housefuls met with in all directions.

Gardenias are such gross rooters that they seem to spurn the control of pots. Almost before the roots reach their sides they cease to thrive or to grow, hence the importance of planting them out. The mere extension of old and formation of new roots seems essential to their perfect health and free blooming. *Gardenias* will not be forced into flower at the bidding or crushing of small pots; on the contrary, the more free and uncontrolled the roots the more freely the plants bloom. So well is this understood by many of the best growers of *Gardenias* that if unable to plant out or shift on their large plants they simply throw them away and start afresh. It is easy enough to feed the old roots, but that will not suffice to keep *Gardenias* in robust health and full flower. To this new roots seem absolutely necessary, and it is found that these are most rapidly produced and kept longest in health in an open border of peat only, resting on a good substratum of thorough drainage.

If compelled to grow *Gardenias* in pots the shifts into large ones should, if practicable, precede root-growth so much and so far as to prevent the roots being matted around the inside of the pots. *Gardenias* in pots should also be overpotted. When this becomes impossible discard the old plants, however fine, in favour of younger ones, for in the ratio in which the plants make roots, so also do they make flowers.

Next to an abundance of roots perhaps a high temperature is the most essential requisite to success in *Gardenia* culture. True, *Gardenias* may be forced to drag out a shivering existence in greenhouse, cold pits, &c.; but where is the benefit to any one? The plants may live, and that is all. But to make them flower freely and preserve them in robust health, a high temperature is essential. Cultivators differ as widely as from 65° to 100° in their definition of a high temperature; but the average range of those who grow *Gardenias* most successfully may be quoted as from 65° to 80°; this tropical temperature not only ensures a superabundance of roots, but strong growth and plenty of bloom.

Abundance of moisture and of food are needed to sustain the strength and vigour of the plants. As to moisture, there are few more effective means of vapourising the atmosphere than by the use of fermenting material. This and the bottom-heat were the secret of the success sometimes obtained in the culture of *Gardenias* in olden times. Now overhead syringings, and the constant damping down of paths, stages, &c., have ensured that the atmosphere shall be kept at or within a degree or two of saturation. The roots are also kept flooded with water during the period of most active growth. Dryness in the air or at the roots is fatal to success in the culture of the *Gardenia*. Even when dryness at the roots is not carried so far as to impair the health or check the vigour of the plants, it may readily result in sending off a whole or a half of the flowers in showers before they open. As to food, the most successful growers give little in the soil. True, some have grown good *Gardenias* in a mixture of loam, peat, and cow manure,

the latter well spent, and in small quantity; but fibry peat is now mostly preferred, and food is given if needful in the form of weak and clean manure-water—that made of cow-dung and soot in weak solution being often used. *Gardenias* thus treated and shaded from the direct rays of the sun, though at other times exposed to as much light as possible, grow with a vigour and flower with a profusion totally unknown under the older system of cultivation. The flowers are also larger and more full of fragrance under these more liberal methods of cultivation, and the plants enjoy complete immunity from the attacks of insects.

New Garden Plants.

ZAMIA MONTANA.*

THIS interesting species was described by Alexander Braun in 1875 from specimens collected by Gustav Wallis in New Grenada in 1873. It was again met with, in 1880, by Kalbreyer. Quite recently Messrs. Shuttleworth, Carder & Co. have imported a fresh stock from Antioquia, a circumstance of some interest to students and cultivators of Cycads, as the species had all but disappeared from cultivation.

The following description is drawn up from the notes and materials of all three collectors. I am indebted to Professor Eichler for a tracing from Wallis' specimen, to Messrs. Veitch and Herr Wendland for part of Kalbreyer's specimen, and to Messrs. Shuttleworth, Carder & Co. for specimens of the foliage of their imported plant (which have enabled me to identify the species), as well as for the stems which they have presented to the Royal Gardens, Kew.

Stem tuberous, 4–5 feet high, 1 foot thick (probably in very old plants); leaves forming an erect terminal tuft, 4–5 feet long; petiole at the base fuscescent, flattened above and $\frac{1}{2}$ inch in diameter, beset throughout with minute scattered prickles; leaflets numerous (eight to ten pairs), the lower more distant, 1 foot or more long, 2–4 inches wide, chartaceous, oblanceolate to linear-oblanccolate, slightly unsymmetrical, narrowing into a very short petiole, apex abruptly acuminate, with usually one prominent and a few obscure teeth; nerves twenty to thirty-five, marked by strong furrows above, scarcely prominent except in dried specimens below. Inflorescence unknown. New Grenada. Moderately shady places in the upper mountain region, 7000–8000 feet.

Regel places this species in his genus *Aulacophyllum*, which principally differs from *Zamia* in the leaves being produced simultaneously and not in succession. The validity of the character requires to be tested by a further study of the species in a growing state. *Zamia montana*, as far as foliage goes, has its nearest ally in *Zamia Skinneri*, from Guatemala, which differs in its smaller, more symmetrical, broadly oblanceolate and sharply denticulate leaves. *W. T. D.*

ZAMIA OBLIQUA† (fig. 72).

This charming species, another of Gustav Wallis' discoveries, was also described by Alexander Braun. It differs from all other *Zamias*, and, indeed, as far as I know, from all other Cycads, by its Chamedorea-like habit. It has a straight, slender stem, of considerable height in proportion to the crown of numerous handsomely modelled leaves. Altogether, the plant has a character of distinction which makes it very acceptable in a collection of rare stove plants.

Stem cylindrical, erect, sometimes as high as 4 feet; 1½–2½ inches diameter, ultimately covered with a smooth or slightly warted pale scarious cortex, marked by the obscure transverse leaf scars. Leaves numerous, forming an erect ultimately spreading terminal crown, 1½–3 feet long. Petiole about equalling the rachis, cylindrical, glabrous, with a few minute scattered prickles. Leaflets about six pairs, 6–9 inches long, 2–4 inches broad, chartaceous, elliptic-oblanccolate, base narrowed into a short petiole; apex gradually caudate-acuminate, margins spinulose-denticulate

* *Zamia montana*, A. Braun, in *Monatsh. Acad. Wiss., Berlin* (1875), p. 376; *Aulacophyllum montana*, Regel, *Botanischer Anzeiger* (1879), p. 141; *Cycad. Revisio* (1879), p. 30.
† *Zamia obliqua*, A. Braun, in *Monatsh. Acad. Wiss., Berlin* (1875), p. 195; Regel, *Cycad. Revisio* (1879), p. 42.

from the middle upwards, upper surface bright green, shining, lower paler; nerves numerous, slender, wholly immersed. Inflorescence unknown. New Grenada: warm region.

Zamia obliqua was originally introduced by Messrs. Veitch. More recently it has been well represented in the collections of Mr. Bull and Messrs. Van Houtte. Good plants are in the possession of the Royal Gardens, Kew. A coloured figure will be found in the *Revue Horticole*, t. 289. *W. T. Thibault-Dyer*. [Our figure was taken some time since from a plant in Mr. Bull's collection, since which time it has considerably increased in size and beauty. Ed.]

ANTHERICUM (HIALANGIUM) GRAEFOPHYLLUM, Baker, n. sp.*

This is a new species of *Anthericum*, allied to the well-known St. Bruno's Lilies of Europe, which was discovered by Dr. Balfour in his recent exploration of the island of Socotra. He brought home the roots, and it flowered with us at Kew for the first time in the summer of last year, but did not develop its leaves till this present spring.

Root of very numerous cylindrical fleshy fibres, old leaves splitting up into copious strong bristly threads. Proper leaves of the basal rosette sessile, lanceolate, under a foot long, $\frac{1}{2}$ inch broad at the middle, narrowed gradually to the base and apex, with 8–9 strong vertical ribs, marked on the glabrous face with transverse bands of darker and lighter green, the edges conspicuously dilated. Peduncle simple, slender, under half a foot long, with several nodes, each with a small scarious lanceolate bract-like leaf. Raceme lax, simple, few flowered, pedicels solitary or in pairs, articulated near the base. Perianth funnel-shaped, white, $\frac{1}{2}$ inch long; segments lanceolate, with three ribs. Stamens rather shorter than the perianth; filaments white, glabrous, rather flattened; anthers small, globose, orange-yellow, ovary globose; style reaching to the tip of the perianth segments. *J. G. Baker.*

DENDROBIUM LUBBERSIANUM, n. sp.†

A very curious new *Dendrobie*, from the grand area of *Dendrobium*—Birmah. In growth it is like a smaller *Dendrobium* formosum. The terminal inflorescence at hand is two-flowered. The flowers are much like those of *Dendrobium cariniferum*, sepals and petals yellowish-white, with a white chin. The lip is much dilated from its cuculate base, trifid, with rounded large side lacinia, and a semi-ovate, blunt, toothed middle lacinia, covered with styliform processes. On the disc of each lateral lacinia there is a emmar blotch, and the same colour is to be seen on the base of the middle lacinia. The anterior styliform processes stand retrose, and are often pectinate or bipectinate. It is dedicated with great satisfaction to Mons. C. Chevalier Lubbers, the able *chef des cultures* of the Botanic Garden at Brussels. *H. G. Kuhn, f.*

EPIDENDRUM COOPERIANUM (Bat.) CALOGLLOSSUM.

No one would venture to accuse Mr. W. H. Fitch of having done too much justice to the beauty of one of those thousands of flowers he has represented in his wonderful perseverance with pencil and brush. Hence we are fully entitled to declare that the original plant, as represented in the *Botanical Magazine*, was a poor thing with its nearly flesh-coloured lip.

There appeared in 1881, at Mr. Day's, a glorious thing, surpassing a fine plant that flowered at Meadowbank in 1872 at Mr. Dawson's, under Mr. Anderson's management. It was the most exquisite colour, so bright and the glorious purple lip entered, it to be regarded as a not much inferior cousin of *Epidendrum Friderici Guilielmi* itself. This plant was bought at a high price by Sir Trevor Lawrence at the Dayan sale. I have before me a very strong plant coming from the same source as that from which Mr. Day obtained it, from Dr. Wallace, the New Bull Company, Colchester. *H. G. Kuhn, f.*

* *Anthericum graefophyllum*, n. sp.—(Nigro hirsuta) caulis crassiusculus denum sulcatus nigro pilosulus; foliis subcaerulis multo cylindricis, foliis verticis in fibras-valde copiosis dissolutis, foveis productis lanceolatis dorso et facie glabris, venis primariis validis 8–9 fasciis, transversalibus pallide et saepe viridibus decoretoe morae conspicue ciliatis; pedunculo brevi simplicifloro 4–6 minutis scariosis bracteiformibus parvis, racemo laxo paucifloro, pedicellis 1–2-nis, perianthii albis infundibularibus; segmentis lanceolatis; staminibus perianthio brevioribus; antheris parvis luteis. *J. G. B.*

† *Dendrobium Lubbersianum*, n. sp.—(Nigro hirsuta) caulis crassiusculus denum sulcatus nigro pilosulus; foliis subcaerulis oblongis apice inaequalibus, utrinque hispidis, racemo terminali oblongo 9-sepalis triangulis acutis carinatis, lateralibus in calyce exsertatis; perianthio albis; segmentis lanceolatis; staminibus aequalibus, labello emarginato distato trifido, lacinia lateribus obtusangulis antrorsum denticulatis, lacinia mediana brevi lobulata imbricata distortulata antice retusa, regione inter lacinias laterales intricata medio sulcata, papillis acutis paucis in ima basi, papillis filiformibus pectinatis bipectinatis antice in basi lacinae mediana. Opt. Lubbers Brunellensium dicitur. Ex Birmah imp. Dr. Fitch. (*v. v. c.*)

MALVERN HOUSE.

THE very interesting collection of Orchids and other new plants, many of which are not yet in commerce, which may any day be seen in Mr. Christy's garden at Malvern House, Sydenham, cannot fail to attract the attention of the plant student, or still more so of those who specially identify themselves with the distribution of new plants. Some very fine examples of *Dendrobium macrotphyllum giganteum* grown in

in flower, and a plant, strange to me, of *Albica data*—a Garlic-like plant with a flower-spike over 2 feet long; also some excellent plants of *Dracyna indivisa lineata*, a good-habited plant for the table. Mr. Christy has also got a stock of the original *Imanophyllum* miniatum imported into England twenty years ago, which quite eclipse a great many of the varieties seen now-a-days in point of colour. Collections of Orchids from the waters of the Amazon, and Australian Orchids, Palms, and other foliage

variety, and *Adiantum Paccotti* will also rank high in its class. The red-stemmed *Selaginella*, *S. rubricaulis*, seems a distinct kind worth growing in every choice collection, particularly for house decoration.

Specimens that are remarkable for rarity, and others that are entirely new, are *Urostigma Vogelii*, in fruit; *Ficus Tabernaemontana*, *Prosopis dulcis*, and *Omphalocarpum procerum*, which is said to be the newest thing in Europe; *Hevea brasiliensis*; *Landolphia Kirkii*, and *L. florida*, curious plants from Central Africa, yielding caoutchouc are also interesting subjects. There is a fine batch of *Phenix reclinata*, imported from the Western States of America, which are as fresh as paint after their journey; and if plants can be brought to this country in such condition by thousands at about one-fourth the price they cost to grow in England it will certainly reduce the prices of these fashionable plants to a figure which will tend to popularise them among a class who, cheap as they now are, can hardly afford to purchase them. The plants arrive in this country in packing cases, looking very little the worse for their journey. *Reporter.*

NEW AUSTRALIAN ORCHIDS.

HAVING made a special journey to South Australia and Western Australia with the intention of working up, as far as possible, the Orchids of the two colonies, I have, in addition to obtaining drawings, &c., of those known, succeeded in obtaining the following nineteen new species:—

Caladenia paniculata, sp. n., Fitzgerald.—A small hairy species, about 3 inches high. Leaf oblong-lanceolate, 2 to 3 inches. Flowers three to six in a flat panicle. Petals and sepals narrow, lanceolate, acute, white, with a central streak of red, and tinged with red at the ends on the outside, about 4 lines long and 1 broad. Labellum not two lines long, 3-lobed, the central lobe lanceolate, fringed with clavate calli, side lobes ovate entire. Calli of the disc about twenty, linear, in two rows united by a long central callus, which extends from the short claw for two-thirds of the length of the labellum. Column winged from the base. Anther with a long point. Western Australia.

Caladenia unita.—A hairy species, from 3 inches to 1 foot high. Leaf linear-lanceolate, from 3 to 6 inches long. Flowers pink, hairy on the outside, two or three on long or short pedicels. Petals lanceolate acute, contracted towards the base, reaching 7 lines long. Dorsal sepal erect, hooded, shorter than the petals. Lateral sepals lanceolate, falcate, acute or obtuse, united from more than one-third to two-thirds of their length, reaching 8 lines. Labellum about 3 lines on a long claw or contraction towards the base, the remainder of the labellum ovate, much recurved, and fringed with numerous linear calli. Calli of disc linear, in two converging lines, but united at their base into a plate. Column winged to the base. The wings produced into oblong lobes on each side of the stigma. Anther with a long recurved point. (This is the only *Caladenia* known to me in which the lateral sepals are united.) Western Australia.

Caladenia plicata.—A very hairy species, about 1 foot high. Leaf lanceolate, 7 or 8 inches long, and 7 or 8 lines broad, sheathing at the base. Flowers generally two, yellowish, with red lines down the centre of the sepals and petals. Petals narrow, lanceolate, acute, 10 lines, sepals about 1 inch, lanceolate at the base for about half their length, then narrow linear clavate, the enlargements at the ends being covered with numerous brown calli. Dorsal sepal erect recurved. Labellum about 4 lines on a long slender claw, 3-lobed, the central red-brown, oblong, denticulate, recurved so as to become plicate and touch the under surface of the disc. Lateral lobes orbicular, reddish-yellow, and fringed with long linear calli. Calli of the disc linear clavate in a densely covered band down the centre of the labellum. Column about 6 lines, much curved, winged from the base in two lobes, and having two oval calli near the base, anther with a short point. (The labellum is constantly moving up and down with the slightest breath of air.) Western Australia.

Caladenia lobata.—A tall, robust species, probably the tallest in the genus. From 1 foot 6 inches to 2 feet, hairy. Leaf oblong, lanceolate, sheathing at the base, about 6 inches long, about 1 inch 4 lines broad. One or two flowered. Petals yellowish with a red line down the centre, linear, taper-

FIG. 72.—ZAMIA OBLIQUA. (SEE P. 460.)

small pots, and which are flowering freely, as well as many others, testify to the success with which Orchids are cultivated in this establishment. The practical evidence which is visible to any one who understands Orchids will be seen in the vigorous growths made since the plants were imported as compared with the puny native growths, which are very diminutive indeed.

But, to the writer's mind, there are other plants more remarkable than the Orchids. It was just evident when I reached Malvern House, and I had the pleasure of seeing a nice specimen of *Nicotiana affinis*

plants, can only be mentioned for the present, as a great portion of them are still unnamed. A curious plant of the *Solanum* family, having seven lobes to each leaf (the variety is new), from the West Coast of Africa, is said to possess some medicinal property for the cure of skin diseases; and there are others—notably a red-fruit one—which is very useful for church decoration. There are *Crotons* from the Fiji Islands, and *Aralia Chabrieri*—the *Aralia* of the future so far as habit and usefulness are concerned. Among Ferns *Davallia gibberosa*, which is to be sent out by Mr. Williams, of Holloway, is a very pretty

ing to a point, about 2 inches. Sepals reaching 2 inches 8 lines, or even 3 inches, dilated for about 1 inch, then passing into long fine points, the dilated portion about 5 lines broad, but reduplicate. Dorsal sepal erect, and much curved forward. Lateral sepals sharply curved upwards. Labellum about 1 inch 2 lines long and 1 inch broad on a long, narrow, elastic claw; three-lobed, central lobe narrow, lanceolate acute, denticulate, reflexed, inflated at the base. Lateral lobes green, narrow, acute, fringed with long linear calli. Calli of the disc linear, crowded for about one-third of the labellum, in two bands, which unite into one towards the base. Column about 9 lines, curved towards the anther, wings dilated into a very peculiar orbicular lobe about the centre of the column. No gland at the base of the column. Anther with a sharp point. Western Australia.

Calanina leptocolla.—A rather slender species, hairy, about 1 foot high, generally two-flowered. Leaf lanceolate, sheathing at the base about 4 or 5 inches. Sepals and petals yellowish. Petals linear, tapering to a fine point, about 1 inch. Sepals curved upwards, linear, tapering to a fine point, dilated about 1 inch three lines. Labellum on a long claw, dark red-brown, about five lines long and two broad, lanceolate, recurved for about half the length; probably the flattest labellum in the genus; denticulate along the edge towards the base. Calli of the disk in four rows, oblong, sessile, except a few at the base, which are linear clavate. Column about six lines, not much curved, winged to the base, deeply winged for about two-thirds of its length near the anther. Anther with a long point. Two orbicular calli at the base of the column. South Australia.

Calanina reticulata.—A rather slender species, hairy, about 9 inches high. Leaf lanceolate, sheathing at the base, about 4 inches long. Flowers one or sometimes two. Sepals and petals yellowish, with a red line down the centres. Petals linear, tapering to a clavate point, about 1 inch 6 lines. Dorsal sepal erect. Labellum about 5 lines, on a long claw, undivided, reticulate, with dark red veins (as in section *Phibechilus*, Dent.), ovate lanceolate acute, margins serrate. Calli of the disc linear clavate, in four rows, the outer rows more or less abortive. Column about 6 lines, slightly curved, winged from the base. Wings dilated towards the anther (but not so much so as in *C. leptocolla*). Anther with a short point. Two orbicular calli at the base of the column. South Australia.

Calanina macrostylis.—A slender species, hairy, about 7 inches high. Leaf linear lanceolate, sheathing at the base, 4 to 5 inches long, 1-flowered. Sepals and petals light yellow, with a red line down the centre. Petals about 1 inch, lanceolate, tapering to a fine point, turned up. Sepals about 1 inch long and 3 lines broad, broadly lanceolate, tapering to a fine, slightly clavate, point. Dorsal sepal erect for three-fourths of its length. Labellum on a short claw, ovate lanceolate, about 6 lines long and 4 broad, yellow, veined with red, the edges thickened for about one-third towards the point, undulate, dark red-brown. Calli of the disc dark red-brown in a broad band extending from near the base to within about a line from the point, linear, clavate, closely packed together. Three or four calli at the base, linear, twice clavate. Column about 5 lines long and 4 broad, very much bent, winged from the base to half way up the anther. Wings on each side of the stigma very broad. Anther with a short point. Two orbicular calli at the base of the column. Western Australia.

Calanina tenuis.—A very slender pubescent species, from 5 inches to 1 foot 8 inches high. Leaf lanceolate, sheathing at the base from 3 to 5 inches. Flowers one to three. Petals and sepals white, with a pink stripe down the centre, light brown towards the end. The colour produced by closely set sessile calli. Petals linear acute, about 9 lines. Sepals broader than the petals and about a line longer. Dorsal sepal erect. Labellum about 5 lines, narrow lanceolate without lobes, point reflexed. Calli of the disc linear in two bands each consisting of four rows. The point of the labellum without calli on the surface but edged with linear calli. Column about 5 lines, very slightly bent, winged from the base. Anther with a rather long point. Western Australia.

Glossodia intermedia.—A slender pubescent species,

about 5 or 6 inches high. Leaf oblong, sheathing at the base, 2 to 3 inches. One-flowered; the outside of the flower pubescent. Sepals and petals about 6 lines, ovate, lanceolate, blunt, glossy lilac-purple. Labellum about 4 lines, linear obtuse, not emarginate, twice duplicate towards the end. A linear ridge on the centre of the disc. Calli at the base not as long as the labellum, linear, with two enlargements towards the end. Column winged from the base and above the anther. (In this species the flower resembles *G. brunonis*. The labellum is more like that of *G. emarginata*, but not emarginate; not simply duplicate, as in *G. brunonis*, but twice duplicate, as in *G. emarginata*. Calli at the base rather those of *G. emarginata* than of *G. brunonis*. Column narrower than either in *G. brunonis* or *G. emarginata*. It flowers later than *G. brunonis*.) Western Australia. *Robert Fitzgerald, Surveyor General's Office, Sydney.*

(To be continued.)

JOTTINGS ROUND BRISTOL.

COTE HOUSE.—To write of a garden where the gardener is an old servant and generally respected by his own craft is always a pleasant duty, and the pleasure is deepened when one finds evidence of skill in the garden along with the qualities above mentioned. Mr. Banister, to whom I refer, has been gardener to H. St. V. Ames, Esq., for many years, and those who have visited the Bristol exhibitions will be familiar with the names of both employer and gardener, both being patrons of the exhibition. Cote House is situated on the Westbury Road, bordering on the Downs, where the air is bracing, and where, if there is much life at all left in one, he feels for the moment rejuvenated. Well, in such a climate one would expect things in good trim, and the result is certainly as good as the most sanguine could expect.

At this season of the year, of course, the glass-houses are the centre of attraction, and thither I wended my way. Upon entering a large plant-house some grand pots of *Lachenalia tricolor* catch my eye; they are grown successfully by planting, from ten to twelve bulbs in a 7-inch pot, and they bear leaves and flowers larger than I have ever seen before. In the vicinities it is needless almost to say that Mr. Banister has the promise of fine crops, and a seedling Vine between *Garden Champion* and *Black Hamburg* is very favourably spoken of, and will no doubt find its way to South Kensington in due time. The Vine has the *Hamburg* leaf and wood, with a tapering bunch like the *Muscad*, but the berries are not, I noticed, quite so oval. The Vine is said to be a free fruiter, the fruit having a sweet *Muscad* flavour.

Ranges of forcing-houses are stocked with Melons and Cucumbers and various other subjects requiring the same temperature. I noticed *Pancratiums*, flowering *Begonias*, and other miscellaneous plants, were particularly well grown for decorative purposes—the order of the day about Bristol. The garden is celebrated for its collections of Ferns, and stove plants generally are cultivated in moderate quantities, chiefly of the useful type. *Calanthe nivalis* is a great favourite, and well it may as grown here. The views from the pleasure-grounds are very fine in clear weather to Portishead and the Bristol Channel, where the training ships are visible in the distance, and Blaize Castle towers glitter in the sunlight. The woods of the latter place are also a charming picture. Leigh Court, the seat of Sir Philip Miles, Bart., M.P., is also within view, and several other places of note; but the trees in the grounds out rival all the others. Here is an old *Tulip Tree* (*Liriodendron tulipifera*) supported by wires, having been uprooted two years ago, and successfully replanted. The tree has a dozen limbs, and at 3 feet from the ground is 12 feet in circumference. A *Wellingtonia* is 47 feet high, and 14 feet in circumference at the ground level; at 6 inches from the ground 13 feet, and at 2 feet from the ground 10 feet 8 inches. Large Cedars are also conspicuous for age and size, and a huge Elm is 22 feet 6 inches in girth a few inches above the ground level. Outside the boundary of the ornamental grounds a very elegant form of Elm was pointed out, which in habit in its present stage resembles an *Acer*. The tree is of huge size, and is a beautifully proportioned pyramid. Of such a place one might write much that would interest; but enough has been said to show that the garden and its adjuncts are furnished with all that can make an English garden enjoyable.

ELMFIELD.—This new and beautifully situated country-seat is owned by A. Shipley, Esq., who is a liberal patron of horticulture, and provides not only good houses in which to grow plants, but also procures rare selections of plants to fill them. The Orchids alone are worth going a distance to see. Probably, however, the *Camellia*-house, built upon the site of the quarry from which stones were procured for building purposes, is the most charming feature of the garden. The structure which covers the site of the quarry is a span-roofed one, in which the central plants are tall *Camellias* and tree Ferns. The space at disposal has been skillfully utilised, and the result is a natural appearance, no attempt being made to alter the jungle-like formation of the place. The irregular arrangement of the rocks at different altitudes, and the variety of plants which have been employed for furnishing the structure throughout seems to have been as carefully selected as they are skillfully cultivated. Tree Ferns, and even *Conifers*, are among those that from natural form or spreading habit relieve or attract the eye from even noticing that a roof of formal shape is overhead. It is a jungle garden under a glass roof—a rockery of Ferns as natural as you will find them in a Highland glen—a carpet of mosses overhung by canopies of Fern fronds, and foliage drooping majestically from stems varying from 3 to 6 or 8 feet high. *Asplenium excelsa* and *Dicksonias* carpeted underneath with mosses, arranged in circular form, are distinct from banks of *Pteris tremula* or *Woodwardia radicans*, which, when planted out in a cool structure grows amazingly. *Cyathea medullaris* is another Tree Fern which succeeds well, and has a grand appearance in a structure of this kind. Other Ferns of striking habit and rapid growth are *Polypodium appendiculatum*, *Neottopteris Nidus*, *Blechnum brasiliense*, and a large variety of dwarf growing kinds, which tend to produce an irregularity in character with the formation of the rockwork.

In contrast with the Ferns there are Palms shooting up from large pockets prepared for them, *Abutilons* trained as pillar plants, New Zealand Flax (*Phormium tenax*), and *Acacia linearis*. The Palms are mostly of the *Chamærops* form and the *Date Palm*, *Phoenix dactylifera*. The conservatory is gay with Palms, *Abutilons*, fine *Azaleas* good in variety and well coloured, grand plants of *Imantophyllum miniatum*, *Cytisus elegans*, flowering *Begonias*, *Gesneras*, *Spiræas*, and *Eupatorium tataricum*, very fine. *Cinerarias*, too, are very showy, as also *Richardias*, *Acacias* in variety, several cool Orchids, *Pimelea spectabilis*, and many others. The Vines in two span varieties are showing well for Grapes, and also contain good examples of *Azaleas* and *Coumtes* of *Haddington Rhododendron*. In the late vineery there are tree *Pæonies* in pots, and other plants that are being brought forward gently. We now reach a range of span-houses for growing select plants and Orchids, and in the first of these there is a miscellaneous stock, comprising a good batch of *Gloxinias* in a forward state, *Urcellina aurea*, a plant with leaves like the well-known *Eucharis* and bearing a profusion of yellow bells with greenish-white tips upon short stems drooping over the sides of the pot. Stove and greenhouse plants are each grown in a house by themselves; of the latter *Stactis profusa*, *Tremandra verticillata*, and *Primula amœna alba*, are very well grown, as also *Pæony Elizabeth* (var. *mountain*), which are charming plants for decorative purposes at this season.

The Orchids fill three houses, and as the collection is a large one, I will just mention only those specimens that are in flower, and that are remarkable as indicating careful cultivation. They are, as follows: *Odontoglossum Roezlii* album, *O. triumphans*, *O. vexillarium*, *O. Halli*; *Pendrobium Wallichii*, *D. chrysotoxum*, *D. Wardianum*, very fine; *D. macrophyllum*, in hanging basket; *P. heterocarpum*, *P. hembrium oculatum*, *P. albo-sanguineum*, *Oncidium macranthum*, with a spike over 12 feet long; *O. Cervantesii*, *O. Weltoni*, *O. Cavendishii*; *Cattleya Trianae Warszewiczii*, *Cattleya citrina* in pans and on blocks; *Lycastes*, fine plants; *Mesospindium sanguineum*, which makes a pretty basket plant; and excellent plants of *Phalenopsis Schilleriana*, one plant of which has a spike with six-and-thirty flowers. The pleasure grounds are prettily laid out, and commanding views of the surrounding country are obtained from them. Shrubs and shrubby borders are in good order, and already there is a good display of herbaceous and alpine plants in the rock garden and in the hardy flower borders. Mr. Smith has been gardener at Elmfield for nine years, and considering

what has been done in the time there must have been a good deal of zeal and activity displayed in communitating so many important garden operations, for be it remembered it is one thing to execute work of a routine character, but quite another thing to construct a new garden out of raw material.

CUCUMBERS BY "EXPRESS."

THAT Cucumbers of the very best quality can be grown by what you have well termed the "express" mode (see p. 427), is hardly to be disputed. It has been said, however, that "there is nothing new under the sun," and the following extracts from a letter of mine, which appeared in your columns two or three years ago, will go far to show that this express method of Cucumber growing is not quite new. The letter alluded to, after mentioning some of the evils to which the Cucumber plant is liable, such as mildew, red-spider, &c., goes on to say:—"In former seasons I have experienced some of these annoyances, but during the last few years I have been entirely free from them, and I am inclined to attribute this result to a somewhat peculiar method of treatment which I will endeavour to describe." . . . "The structure here (Culford), which generally furnishes an abundant supply of Cucumbers during at least nine months of the year, is a small lean-to house, about 20 feet in length and 9 feet in width, with a south aspect, and the roof, which is fixed and without any openings, is at an angle of about 40°, glazed with large squares of sheet glass. The plants are trained to wires stretched under the roof at a distance of 16 inches from the glass, and to afford a slight shade during the summer months the outside of the glass receives a thin coat of whitewash. But notwithstanding this precaution, the plants very frequently became unhealthy long before the season was over, so that some years since the plan of keeping the house almost entirely closed was resorted to and this plan has in all respects proved satisfactory. The ventilators in the front and back walls are now only used during the early stages of the progress of the plants, when, with the view of keeping them as robust as possible, air during favourable weather is admitted; but as soon as the Vines have fairly covered the roof the house is kept quite close, and during very warm weather the plants are syringed not less than six or seven times each day. The atmosphere of the house is consequently surcharged with moisture, while the temperature at the same time frequently exceeds 100°, and in such an atmosphere and temperature it is needless to say that neither red-spider, aphid, nor mildew can exist, while visitors or others who may have occasion to enter the structure do not care to prolong their stay therein. This condition of atmosphere and temperature, however, appears to be that best suited to the production of Cucumbers of the best quality. Being so quickly grown they are quite free from anything like bitterness, and are as crisp, succulent, and digestible as can be desired. Neither does this fast treatment appear to have the effect of prematurely exhausting the plants, which from March until the present time (middle of November) have furnished abundance of fine fruit, and will most likely continue to do so until the end of the year. Under this treatment, too, the foliage throughout the season remains clean and healthy, quite free from insect pests and disease of all kinds. The plants receive very little stopping or thinning out of the shoots. When the leading shoots reach the top of the house they are stopped; after that operation the shoots as they are produced are crossed over each other in any way which is most convenient, and tied to the wires, so that the roof is always covered with clean healthy foliage. The use of the heating apparatus (hot-water pipes) is generally discontinued about the middle of June, and is again had recourse to early in October."

I cannot now state the precise time which elapsed from seed sowing to fruit cutting, nor the weight or number of fruits cut, further than to say that this was always found to be more than sufficient for the demands of a large establishment. I may also say that the surface of the bed in which the plants were growing generally presented a network of white healthy roots, and slight surface-dressings of rich soil, mixed with snot, were from time to time applied to it, and the water used was from a rain-water cistern, into which a portion of the drainage from a stable-yard found its way, so that the water was always more or less enriched by manurial matter; while that

used for the purpose of syringing the plants was, of course, pure rain-water, which had been for hours in the structure, and acquired a similar temperature. *P. Grieve, Eury St. Edmunds, April 3.*

HELICOCORYNE RAMOSA.

THE figures of different species of Moulds, which are given by Corda in his *Prochilora*, are so beautiful and extraordinary, that many have thought that they were greatly exaggerated, if not altogether imaginary, inasmuch that Corda himself told me, "People imagine that I have seen them in my dreams." We have had an opportunity of verifying several of his species from specimens which he himself communicated. We have, however, now to lay before our readers, one, if possible, more beautiful, and certainly more curious. The Mould in question was sent to us from New York as a new species of *Macrosporium*, but unfortunately in the specimen examined by the writer of this notice and Mr. Broome, the spores were all detached, and looked so much like some insect that we doubted greatly whether it was vegetable at all. The fallen spores resembled closely those of *Sporidium elegans*, especially the older ones. Mr. Broome, however, found that they unrolled into a spiral. With a view to gaining further information as to

FIG. 73.—HELICOCORYNE RAMOSA.

their nature, specimens were sent to Mr. W. G. Smith, who found the spores attached, as we do now in the specimens which he has returned, with a suggestion that the plant may be referred to Corda's genus *Helicocoryne*, which indeed differs only in the spire being more unrolled. The fungus, which is of a pale olive tint, forms little tufts on old deal shingles, the spores themselves being nearly colourless, or much paler than the threads.* The species, whose characters are given below, may bear the name of *H. ramosa*. The spores on a partial examination appear as if they were beaded all round, a structure which is illustrated by the figure quoted above, and is merely an optical delusion. It is possible that Corda was deceived as to the structure. *M. F. Berkeley.*

CORREA CARDINALIS PLANTED OUT.—Most people are acquainted with this fine old plant under pot culture, nor indeed is a well-grown specimen of it ever likely to be despised. The well-known scarlet bells, which are produced freely upon a healthy plant, leave an impression upon the mind which is not soon forgotten; but planted out and grown in a natural way there is a complete transformation. In the conservatory at Elmfield, near Bristol, the seat of A. Shipley, Esq., a standard has been planted out in rockwork, which is now adorned with its bright scarlet bells, and is the prettiest of many pretty objects in the same house.

* *Helicocoryne ramosa*, Br. and Smith.—*Floeris ramosa* triloculatis; sporis ellipticis e spiris simpliciter convolutis.

ASPARAGUS.

OF all vegetables this is the most delicious and wholesome, and yet there are thousands of gardens belonging to the well-to-do classes in which there is not a bed or plant of it to be found, and in many where there are it is not grown to anything like the perfection it might be, as in the majority of cases the plants are either overcrowded or are treated in a way by which it is next to impossible for them to become fine and strong. It is often remarked that they do so-and-so better on the Continent, and there can, I think, be no question but that the French do beat us in growing Asparagus, as witness those fine bunches that are sent over to Covent Garden, the heads in which are of great size, and are the admiration and wonder of many beholders. It is quite certain that if the French cultivators pursued the same system as prevails here in the management of our plantations, they would not excel in the manner they do, as they have neither a more fertile soil nor a more favourable climate, and the whole secret lies in giving the plants more room and feeding them well. This being so, there is no reason why we should not follow the same course, and produce just as fine heads, for it is not to our credit that we should have to depend on others so largely for the supply of an article of food that we might as well grow for ourselves.

We talk of farming interests being bad, and of land going out of cultivation because it does not pay, while Asparagus and many other vegetables are only to be had by the few, the prices being such that only the wealthy can buy them. If Asparagus were only planted to anything like the extent it might and ought to be, a ready market would be found for all that could be grown; and I am convinced that a third of the prices now charged would pay well, and people in towns would be able to enjoy an article of diet that many among them hardly know the flavour of, as the heads can be cut, bundled up in small compass, packed, and sent from afar. Another advantage in cultivating Asparagus is, that beyond the cutting, it entails little or no labour after planting, beyond keeping the land clean, as once the plantations are formed they last for a lifetime, and the plants grow finer and stronger with age. The soil that suits Asparagus best is that which is of a deep loose character, for the roots, being large and fleshy, can only ramify freely in a medium that is free and open. In many districts plenty of such land is to be seen, especially near the sea coast and in valleys near rivers, like those in the neighbourhood of Colchester, where Asparagus is grown better than in any other part of England. Although Asparagus delights in a soil like that referred to, it objects greatly to that which is wet with stagnant water, as in ground in such condition the roots rot. I have seen it done remarkably well in moist greasy sand, and no doubt where land of this nature can be had near towns and irrigated occasionally during the summer with sewage, Asparagus might be grown to a very high state of perfection.

The best time to plant is immediately the crowns begin to start, as then they can be handled readily, and the plants go right off into full growth without any hindrance. Where plants are on the spot and can be taken up and got in quickly the planting may be done when they are from 6 inches to a foot high, and if the soil is washed in about the roots by giving a heavy watering they do not flag or seem to feel the check, but quickly become re-established.

To begin with, one-year-old plants are the best, and these should be dug up with a fork and lifted carefully, so as to preserve the roots from injury, and in replanting it is necessary to spread or lay these out so that the points incline down, and then to cover them with about 3 inches of soil. The readiest way to plant Asparagus is to open a shallow trench a foot or so wide, in which the plants can be placed and the earth returned in a speedy and satisfactory manner. Previous to the planting, however, the ground should be trenched, and during the operation have plenty of manure worked in. If the land is at all inclined to be stiff and close it is better to have the manure rather long and strawy, like that generally to be had from stable yards, as the tendency of such is to keep the soil open; but where it is already light, cow-dung or night-soil will be the more preferable. With ground prepared in this way the plants should be put in rows about a foot apart, and the rows ought not to be a yard from each other. Planted in this way, with plenty of room, the roots have a fair chance

to find what they want without starving each other. In beds they become massed together, and under such circumstances it is impossible for the plants to develop fine crowns.

What injures *Asparagus* very much in beds is the cutting down and digging out the alleys between—a practice still in vogue with some, although it is fast dying out. Another thing that weakens the plants materially is cutting the heads late in the season, by doing which the plants are exhausted in their efforts to throw up others, and have not time to recruit. Taking one season with the other, and speaking broadly, the end of May is quite as late as it is advisable to cut *Asparagus*, and it is a good plan to cease with a portion of the beds or plantations before then, and allow the other to grow. Those plants furnishing the late supply one year may be rested the next, and so on; and if this is done it will have a very beneficial effect. In spring, just as the heads are coming through, a slight sprinkling of salt over the ground does good, as it not only destroys weeds, but it stimulates and improves the flavour of the "grass." When the tops are cut and removed in the autumn, a dressing of short rotten manure should be given, and if the crowns of the plants are near the surface, some light soil may be thrown over too. *J. S.*

CRAIG-Y-NOS CASTLE.

CRAIG-Y-NOS CASTLE, the charming Welsh resort of the ever-popular Madame Adeline Patti (see pp. 465, 466) is situated about 21 miles from the busy town of Swansea, on the banks of the River Tawe, in the county of Brecon. The name *Craig-y-nos* is purely Welsh; rendered into plain English it signifies "Night Rock," so that it would read "The Castle of the Night," or "dark rock" or "mountain," no doubt in allusion to the dark mountains immediately surrounding it. It is, at all events, extremely appropriate. A more secluded or romantic spot it would be difficult to find—it is seclusion itself! Hence the charm, no doubt. Away from the glare and turmoil of constant excitement. Here solitude prevails, here are found rest and quiet.

Craig-y-nos is approached by the Midland Railway. The nearest station (Pen-y-will) is situated on a high mountain ridge, some 800 feet above the level of the sea, a very cold and exposed station indeed, and is stated to be half an hour's walk distant.* A trusty guide, however, and stout legs are required to accomplish it in an hour. There is no regular road over the bare mountain side, and often long *cloums* have to be made, as on the occasion of our visit, when the storm of the previous week had lashed the little river into a perfect torrent, carrying away the bridge, the newly-finished river-wall, and lowering the natural bed some 3 or 4 feet directly in front of the Castle. The walk is, however, extremely interesting to any one having a botanical turn, a great many charming alpine plants being met with growing between the chinks of the limestone rocks. Ferns abound, the pretty little *Asplenium Trichomanes* making a perfect wall of verdure; also the rarer *Cystopteris fragilis*. In shady nooks *Saxifraga hypnoides* forms quite a carpet. On the opposite side of the valley the pretty green and rare *Asplenium viride* is to be found in considerable quantity.

Arrived at the Castle—which, as will be seen from the illustration on p. 466—is situated on a plateau some 100 feet above the river. Looking from here one is struck by the stillness of the scene. There is the tortuous river below, little more today than a great highway of boulder-stones, but at times a swift mountain torrent. Beyond, and on either side, very little but the bare and rugged mountains meet the view, with flocks of the pretty Welsh mountain sheep browsing on their steep sides. A little to the left *Danyrogaf* Cave, containing some beautiful examples of stalactites and stalagmites—those wondrous silent works of Nature in the bowels of the earth, formed by perpetual dripping from the calcareous rocks—will well repay the exercise and nerve necessary to reach it. It is regretful to find that even here some wretched beings are base enough to destroy the beautiful—that which they come to see.

But to our text, and the object of our visit, *Craig-y-nos*, on becoming the property of Madame Patti,

some few years ago, presented a very different appearance from the *Craig-y-nos* of to-day. Considerable additions were necessary, and have been made to the Castle itself. It is a matter of great regret that the architect should not have constructed the additions after the style of the original. The gardens, and all that pertain thereto, are entirely original, and have been formed and constructed from the plans and under the superintendence of Mr. William Barron, Garden Architect, &c., Sketty, Swansea, to whom Madame Patti intrusted the work. Mr. Barron is, we understand, a pupil of the late Sir J. Paxton, at Chatsworth, nearly forty years ago, but is no old-school practitioner—on the contrary, a glance at the light, elegant, and beautiful designs here shown will, we venture to say, place him as one of the first of the day.

A special feature here are the steep grassy slopes or terraces in front of the Castle; these, although not yet completed, were a work of no mean character—the quantity of soil required in their formation being astonishing. How much better these grassy slopes look than the ordinary inevitable terrace walling, and how much less costly! We have before noted Mr. Barron's mode of forming these grassy slopes in other parts of the country, and it appears to us his style is particularly pleasing, inexpensive, and quite unique.

The conservatory attached to the Castle measures 80 feet by 27, having a ridge-and-furrow roof, the side-lights with glass near to the ground all forming doors that may be opened at pleasure to go out on the terrace at any point. No staging is used, the plants being placed in groups as required, or cleared away altogether, as on the occasion of our visit, and used as a banquetting-room. Creepers plentifully adorn the roof and pillars, the whole presenting a very charming appearance. A glass corridor, 50 feet long by 11 feet, leads from the conservatory to the winter garden, which measures 80 feet by 60. This, which is also ridge-and-furrow roofed, and constructed in the light and elegant style of the conservatory, covers an irregular or undulating piece of ground. A small fountain adorns the centre, but the arrangements of the plants are not yet completed; when they are so this winter garden will be unique in its way, and cannot be but charming. The heating arrangements throughout are of a very complete and efficient character: four rows of 4-inch pipes going round the conservatory covered with ornamental grating, four rows along the corridor, and six rows round the winter garden. The whole, as well as the ranges of forcing pits and houses, vineries, &c., being heated throughly by boilers 300 feet distant, having 27 feet of a rise. But of this we may speak hereafter.

FLOWERS IN SEASON.

MAGNOLIA CONSPICUA.—A Chinese tree of medium height, with deciduous leaves, flowering in early spring before the leaves expand, and producing from the ends of the young shoots obovate or pear-shaped erect flowers, pure white, with a delicious fragrance. Petals, each about 3 inches long, leathery, oblong or oblong-obovate obtuse. Stamens crowded in many rows round the base of the elongated spike bearing the carpels, filaments fleshy, lilac at the base. It is curious to note how, as in other *Magnolias*, sepals, petals, stamens, and carpels, instead of succeeding one another in rings form a series of spiral coils around the prolongation of the axis of the flower. The Chinese name, *Yulan*, is said to signify a Lily, and the vase-shaped white flowers, which form so conspicuous an embellishment of the tree in spring are, indeed, not unlike Lilies, taking the word in its vague general sense. Representations of the flower are common in Chinese and Japanese drawings. The species is cultivated in Japan, and is said to have been introduced here in 1789.

LONICERA SEMPERVIRENS.—A charming climber, hardly enough to stand our climate out-of-doors, but amply deserving a place in a cool greenhouse. The upper leaves are inseparable at the base, forming a flat transversely oblong plate, pale green above, glaucous beneath, through the centre of which the slender stem seems to pass. The long trumpet-shaped flowers are borne in two or three tiers or whorls, each tier with six flowers, and separated from its neighbour by a slight space. The little green flask-shaped ovaries are surmounted by a very small 5-toothed calyx, and then comes the slender curved

tubular corolla, nearly 1½ inch long, of an orange-crimson colour. The limb of the corolla is yellowish, with five short roundish nearly regular lobes, beyond which both stamens and style protrude. It differs from the common *Honeysuckle* in its nearly regular flowers, which are scentless; on the other hand, its colours are much more brilliant. Native of the North-eastern States of North America, but though long ago introduced gardeners do not seem to recognise its value as a greenhouse climber.

MARANTA WARSEVICZII.—We noticed this in bloom, under Mr. Hudson's care, at Gunnersbury lately. It is one of the most ornamental of stove foliage plants, having long-stalked, oblong acuminate leaves rounded at the base, dark velvety-green above, with light coloured patches near the midrib, and with the fine veins also whitish; the under-surface is softly downy and of a rich violet colour. The leaf-stalk is long, membranous, and sheathing for two-thirds of its length. The dense flower-spikes emerge from the axil of a leaf-sheath, and consist of an oblong mass of densely overlapping, broadly ovate, acute, boat-like bracts, cream-yellow beneath, edged and tipped with lilac; each bract protects a whitish flower, whose lips protrude beyond their recurved points.

LATHRÆA CLANDESTINA, &c.—From Biarritz we receive specimens of this very beautiful and very remarkable plant. It is a parasite, like our *Broomrapes* (*Orobanchæ*), and is of course nearly allied to the *Lathræa squamaria* of our woods, like which it has roundish, fleshy, thick leaves, but the flowers in this case are differently arranged, much larger, and of a lovely violet-blue colour. We fear the plant at present defies cultivation, though there is no reason why the attempt should not be made to import the plant growing on its foster-parent. The common *Lathræa squamaria* has been sent to us by several correspondents. It grows on the roots of Hazel and other trees, and is a leafless white parasite, with a dense spike of pale lilac flowers all turned to one side. It often passes for an Orchid with those who think everything a little out of the common way must be an Orchid.

PLANT PORTRAITS.

ANOPHOXYTIUM INCANUM, E. Morren, Belg. Hort., t. xi., 1881.—A singular Brazilian epiphytal tufted Bromeliad, with lanceolate acuminate broad based leaves thickly covered with coarse white down; racemes pendulous compact, bracts silvery, petals rosy. It is the *A. Rollissonii* of gardens, and is also known as *Tillandsia Gardneri*, *T. incana*, and *T. argentea*.

BEGONIA DISCOLOR, Illust. Hort., t. 434.—A set of six hybrids between *B. discolor* ♀ and *B. rex* ♂, viz. 1, Madame Joseph Moens, silvery white, with green reticulations towards the margins, and a green disc; 2, Madame Charles Weber, green ground, spotted with white; 3, Madame G. van Meerbeeke, silvery, with a narrow green edge and a central green disc running out along the veins; 4, *Souvenir de Madame la Baronne de Bleichroder*, disc and broad margin brownish-green, central portions silvery; 5, Madame Funck, disc and broad margin light apple-green, intermediate portion silvery; 6, Baron A. de Vrière, disc dark green, central silvery, margin broad, dark green, silver-spotted.

CRYPTANTHUS BEUCKERI, E. Morr., Belg. Hort., 1881, t. xvii.—A curious tufted Bromeliad, native of Brazil, with ovate acute leaves, the outer with long broad stalks, the inner nearly sessile, sharply toothed, salmony-orange, barred with transverse blotches of green. The flowers are white, crowded in the centre of the tuft of leaves. *Hort. Beucker.*

MASCARENHANSIA CURNOWIANA, Garden, Feb. 11, 1882.—A very pretty stove Apocynaceous climber, with lanceolate leaves and large bright rose corollas, with a slender tube and spreading 5-lobed limb with lanceolate segments. Messrs. Low. See *Gard. Chron.* 1881, p. 283, vol. xvi.

SEMPERVIVUM MOGGRIDGEI, Hort. De Smet, Bot. Mag., t. 6610.—A form nearly allied to *S. arachnoideum*, but differing in the longer leaves and larger flowers.

STERCUARIA DISCOLOR, Bentham, Bot. Mag., t. 6608.—An East Australian tree, with Ivy-like leaves, hoary on the under-surface; flowers in spikes, calyx funnel-shaped, 1½ inch long, leathery, rosy, 6-lobed, stellately hairy. *Hort. Kew.*

* The station for carriages is some 7 miles distant.

The Herbaceous Border.

PÆONIES.—These may, I think, be justly regarded as the kings and queens among herbaceous plants, as they are not only very showy in character, but grand in the extreme, and gorgeously beautiful when clothed with their bold massive blossoms. The tree kinds are very fine, and produce a striking effect on lawns, but they lack the richness of colour of the herbaceous sorts, some of which have deep crimson flowers of great size and substance, and almost as round as a ball. The best, however, in my opinion, are the semi-doubles, which are not so massive and stiff-

ing into growth it is a good time for dividing and planting, although this would have been better done earlier, before the crowns had got so forward, as in travelling they are apt to be bruised or damaged unless very carefully packed and handled, and if the shoots get broken or injured the plants are weakened and thrown back for a season. Although Pæonies will succeed in almost any soil, they do best in that which is in good heart and deep, and therefore before planting large holes should be dug and some rotten manure worked in at the bottom. This will help to feed them for a long time after they become established, and enable them to form strong crowns, on which their free flowering depends. Being large-growing plants, they should be planted at the back of any border or the centre of a bed, and there

side of woodland walks and in other kindred positions than this pretty spring flower. Let not the fact that it is common in many districts militate against its employment for the purpose named. It is when it can be seen in masses, the plants growing thickly and covered with pretty nodding flowers, that its sweet and unassuming beauty can be best appreciated.

In some of the woods about Watford there are thousands of plants in large patches, or less crowded, silencing the banks of hedgerows in the pleasant spring time. An inspection of the flowers will show many of them have faded tints of rose, some deeper and some paler, and double forms are also to be met with. The long roots are to be lying almost on the surface, receiving sustenance from

FIG. 74.—CONSERVATORY AT CRAIG-Y-NOS CASTLE, BRECON: THE RESIDENCE OF MADAME ADELINA PATTI. (SEE P. 464.)

looking, and the blooms of these are valuable for cutting to use as single specimens in glasses, where, with a portion of their own foliage, they are charming to look on, and in these days of æstheticism are regarded as the correct thing to have in a room. One of the most choice among them is *P. Cherub*, which has the outer petals carmine, and the centre pure white, the contrast between the two being both striking and pleasing. *Duchesse d'Orléans* is also a very showy kind, having outer petals of a rose-lake colour, with salmon centre. *Victoria Modesta* has outer petals of the same shade as the last-named, and pink centre tipped with white. *Desdemona* has blooms of a clear rose, very large, and double. *Archangel* is a fine sort, rose-lake tipped with white; and *Potesi* and *Whitley* are both desirable sorts, and the old *officialis rubra plena* is the richest and best of the crimsons. As Pæonies are just start-

allowed plenty of room to spread and develop.
J. Sheppard.

RANUNCULUS ANEMONOIDES.—This neat and distinct alpine plant, obtained at the beginning of last year from Messrs. Fröbel, is now flowering freely in one of the top pockets of a limestone rockery. The leaves are crimped like Parsley, and the flowers remind one of those of the common Daisy, but with broader and fewer petals, and are more than an inch across, white, with a slight tinge of rose. As both flowers and leaves are procumbent it does better, as all alpine plants do, for a surrounding of fine gravel, which keeps the surface of the soil healthy, and the flowers from being splashed. *C. Wolley Dod.*

ANEMONE NEMOROSA.—It would be difficult to name a subject better suited for naturalising by the

decaying leaves that cover them in autumn and winter.

The practice of raking up the leaves in autumn in woodland walks, and on the grassy banks and verges of semi-wild places, plays havoc with wild gardening. Daffodils, Primroses, Anemones, &c., are all gathered with the leaves, instead of the leaves being left for sustenance and protection. The pretty mauve-coloured *A. apennina* should be mingled with *A. nemorosa* where it can be done. It is one of those subjects that require to be let alone; then, in a suitable place, it will grow into large patches, and bloom with great freedom. All that is required is to keep the patches free from weeds and rubbish accumulations, that will retard the growth of the plants. The leaves should be allowed to accumulate and decay, in order to nurture and give strength to the clumps.

Orchid Notes and Cleanings.

WORK IN THE HOUSES.—Among the Orchids that are really useful to the gardener the deciduous *Calanthes* deservedly rank high, and may be grown successfully by any one who possesses a stove or a well heated pit. It is not advisable to start these into growth too early in the season or before we get the days longer than the nights, but where the plants have had a good rest without any water at the roots they will now be showing signs of activity, and should not be allowed to get too forward before they are reotted. The bulbs may be grown singly in 48-pots, or three bulbs may be grown in a 32-sized pot, and when it is desired to make large specimens of them it will be better to start the plants in small pots, and keep them in these till their growths are well advanced when six or eight healthy bulbs should be placed in a large pot, and when their flowering period arrives they will be very effective. The soil we prefer for *Calanthes* is sound fibrous loam with all the earthy matter threshed out of it. To this add a small quantity of dry cow-dung and a few nodules of thoroughly dried or partially baked clay, and a dash of silver-sand. As the potting proceeds, a few pieces of charcoal should be worked through the soil round each plant, and the soil should be pressed moderately firm in the pots, so as not to hold too much moisture when the plants are first started, otherwise the foliage is apt to get diseased, and when this state is brought about the plants do little good afterwards. A position close to the glass, with a night temperature of 65° to 70°, and an advance on this during the day with a moist atmosphere, is what suits the *Calanthes*. These remarks apply to *C. Veitchii* and two forms of *C. vestita*; but the beautiful *C. v. Turneri*, which is a later bloomer than the others, may not yet be out of flower, but when it is ready for potting the treatment given above will suit it. About this season of the year we are generally troubled with a small colony of green-fly in the cool-house, and it is not safe to recommend fumigation to the inexperienced without a caution, and the caution is, never to fill the house so full of smoke that you cannot see perfectly from one end of it to the other. These fumigations will need to be repeated about three times with two or three days interval between, and if they are carefully carried out the *Odontoglossums* will not receive the slightest injury. Where thrips are troublesome on the *Masdevallians* these should be carefully sponged over at once, repeating the operation after an interval of a week or so. During hot sunny days it will now be necessary to damp down the houses more frequently than hitherto, and the ventilation should be attentively managed so that no unnecessary loss of atmospheric moisture held in suspension in the house occurs. *J. Roberts, Gunnersbury.*

FLOWERING ODONTOGLOSSUM ALEXANDRE.—It may interest Mr. E. Vervae to know that spikes of this *Odontoglossum* have been produced in this country with as many as forty-five flowers on a single spike. We had a spike here some time ago with exactly the above number of flowers, all open at one time; the spike showed forty-eight flowers, but three failed to open. Another plant here produced a spike of thirty-six flowers, which were all open at one time, and the flowers in both cases were larger than the best *O. Pescatorei* flowers I have ever seen. Both spikes had several branches, and it is hardly necessary to say, that the plants that produced them were exceptionally well rooted. *J. Roberts, Gunnersbury, near London.*

THE ORCHID ALBUM for March contains coloured figures of *Cattleya superba splendens*, *Paphia cristata*, *Odontoglossum Andersonianum* and *Cypripedium polium* x. These will be further referred to in our list of plant portraits. Among miscellaneous matter we may call attention to a note on a variety of *O. crispum*, with canary-yellow flowers, which has appeared in the collection of G. Hardy, Esq., Timperley, Cheshire.

CYMBIDIUM EBURNEUM UNDER COOL TREATMENT.—We have at present some specimens of this lovely Orchid in flower which have been subject to

comparatively cool treatment. Our practice is to grow them with *Odontoglossum cirrosum* separate from *Odontoglossum Alexandrie*, always keeping the house 5° warmer than for the *Alexandras*, which practice speaks for itself here at present, as we have a batch of six *cirrosums* which were bought last June in very small thumbs, and which are now a mass of flowers. We have had plants of *Cymbidium Mastersii* in flower at Christmas, treated in precisely the same way as *C. eburneum*. *W. B. G.*

MALFORMED COLOGNE.—I send you a very handsome deformity of *Cologne cristata*. It is from a spike of the plant exhibited at our Sevenoaks Spring Show lately, by Mr. Burt, gardener to H. B. Millward, Esq., Shoreham Place. The plant was a well-flowered 2 feet specimen. The flower has three lips, two of which are joined for three-quarters of an inch; three columns are distorted into one, and it has ten sepals and petals, thus making five more. Mr. Burt had not noticed it, but when I pointed it out to him he kindly allowed me to send it you. *L. B. Greenhalgh, Rossett, Srewnock.* [At first sight it appeared as if two or perhaps three flowers were joined together, some of the parts being squeezed out of shape, or even jostled out of existence altogether. Such, however, is not the true explanation. The appearances are due to a twisting of the axis of the flower during growth, to an increased number of parts and to changes in their forms. The parts of the flower instead of being in a ring are arranged in spiral sequence. There are three sepals, three petals, three lips, as described by our correspondent, then another petal, then a three-fold column, as described above, from the front of which projects another petal. The ovary is of the ordinary character, one-celled, with three parietal placentas. The flower is so distorted that it is difficult to reduce it to its proper symmetry, but the three stamens are one of the outer series (the others being wanting) and two of the inner series, while the petal-like outgrowth from the front of the column may possibly represent the third stamen of the inner row. *Ed.*]

WALLFLOWERS.

AMIDST all the varied introductions and novelties of the past fifty years the Wallflower still holds its own as one of the most loved of garden flowers. There was a time in its history when it had little else to commend it to public favour but its sweet perfume. It is true that these garden flowers were neither so numerous nor so beautiful as they are now. Still the Wallflower was rather a poor thing as judged by our knowledge of its present merits, for, like many other plants, it has had to advance in the march of improvement, and keep abreast of its garden competitors. Our forefathers would have indeed cried "Eureka!" could they but have seen the superb deep reds and the large golden yellows of our time—colours so rich and yet so defined as to evoke our warmest admiration. Our market growers, who find in the dark red Wallflowers the best of all flowering plants for their use, have by dint of constant selection almost converted that kind into a winter bloomer, for if, as during the past winter, the season be open, it is indeed a source of surprise and disappointment if the plants do not commence blooming in November, and continue to do so all the winter, and finishing off their latest flowers by the end of March. The Wallflower now having, in addition to its perfume, such rich colouring, is, therefore, for its season a most popular flower, and always sells at a fairly profitable price. With the advent of warm days comes to the red Wallflower change and deterioration. The deep hues become pale or steaked, and the glory of the flower departs. This inevitable result naturally compels its early blooming, and the encouragement of this faculty has been repaid. Now the rich, clear, golden yellows of the Tall Yellow are singularly constant, and fade or turn only under great heat-provocation; but these kinds naturally succeed the dark reds, and it is yet inexplicable that market growers have never taken to growing these yellows also, as it is an undoubted fact that they always excite the warmest gratification when seen blooming. It may be that the fear of contaminating the old market stock is one of the primary causes of this apparent neglect, and there is good reason to fear such a result if the two kinds are grown in juxtaposition, but it need not result if only ordinary care be exercised in that respect. [We may add that a plant of the wild or naturalized form of *Cheiranthus Cheiri*, taken by us from the old walls of Canterbury, has after cultivation in rich moist soil for some years developed into a plant closely like the Wallflowers of the market gardens. *Ed.*]

The Flower Garden.

CALCEOLARIAS of the type of Golden Gem and *Aurea floribunda*, although not well adapted to enter largely into combination in geometrical arrangements on account of the uncertainty of their duration through disease or other causes, are yet very beautiful and effective when confined to beds in suitable positions and especially prepared for their reception; such beds should be so situated as to be shaded from the mid-day sun, which is often very destructive, and should be carefully guarded against, and some time before planting time the beds should be thoroughly well trenched up, and if the soil is naturally light a portion should be removed and good strong holding loam substituted, and a good layer of rich cow-manure introduced during the operation of trenching about a foot below the surface, which will tend to keep the bottom cool, which is a most essential condition. The plants can usually be taken up from the pits with a good ball of earth and ought not to miss their moving. After planting, a slight layer of cow-manure all over the surface will prevent too rapid evaporation, and by frequent watering where drainage is good a grand bloom is produced for a long season. Isolated plants of these and the more shrubby sorts may now be introduced into the mixed borders with good effect.

PLEASURE GROUNDS.—The general routine of mowing, rolling, edging, and sweeping may now be said to be fully entered upon, but in order to give a finished appearance to all such work it must be supplemented by a careful attention to the gravel walks, the edges of which must be carefully re-cut, the surface of the gravel slightly picked up, and a coat of new gravel spread over the top, which should then be trodden over and raked level, and finally rolled at intervals until it has become consolidated. Nothing contributes more to give a well kept appearance to lawns and pleasure grounds than a strict attention to these apparently trivial matters.

HARDY FERNERY.—I noticed this briefly last month, but since then I find that the new fronds are pushing up fast, and as these are usually very brittle and tender it necessitates immediate attention to the rough work of overhauling and dressing before they are too far advanced. The old fronds should be removed from the evergreen sorts, the size of any which are overgrown reduced, the surface pricked over to remove weeds and extraneous matter, and then a good dressing of leaf-mould, loam, and peat in equal quantities and sifted applied; this should then be forked in slightly, and if the colour is not objected to, a layer of cocoa fibre over the whole surface will prevent evaporation and is peculiarly grateful to the Ferns.

ROCKERY.—So many interesting plants are advancing into flower here that the operations before recommended as attendant upon neatness and cultural care cannot with safety be delayed any longer. It may be of some interest to those who are fond of this very interesting section of flower gardening to notice a few of the most conspicuous plants in flower at the present time (April 2); and here I must give the palm for stamping a distinctive character to the *Erica carnea*, *E. herbacea*, and *E. mediterranea*, which have been in great beauty for some time. Next to these the *Aubrietia purpurea*, *A. purpurea grandiflora*, and *A. Ghiesbreghtiana* are very conspicuous and long flowering; *Anemones* of several cultivated kinds but particularly *apennina*, conspicuous for its bright blue flowers; and by way of contrast the ever-flowering *Lithospermum prostratum*, with dark blue flowers; *Pulmonaria virginica variegata*, very striking and pretty; patches of *Ajax minor*, *Epimedium alpinum*, *Andromeda floribunda*, *Saxifraga cuspidata*, *granulata fl.-pl.*, *cordifolia*, and several others; *Hieris sempervirens*, *Mertensia pulmonarioides*, *Aralis albidus*, *Primula purpurea*, very fine; *Polyanthus* and *Primroses* of many colours, both double and single; *Corydalis tuberosa*, *Lathyrus purpureo oculatus*, and several others; thus showing what an interesting display of flower can be obtained in a comparatively small space, and the best of it is that all those I have enumerated will flourish in ordinary soils and under general cultural care. There are many choice sorts

which require different soils and very peculiar treatment, and unless they are made a speciality, to the neglect of many other matters, require more time, trouble, and attention than can usually be afforded. *John Cox, Redleaf.*

The Pine Stove.

THE PINE STOVE.—With increased light and longer days plants in all stages of growth will make more rapid progress. Keep fruiting-houses up to 70° at night; this is sufficiently high for the present, owing to the cold nights prevailing. These figures may be increased 10° to 15° by day, and let the house be closed early, so that the temperature may rise to 90° for a time. Attend to the atmospheric conditions, and see that the damping is thoroughly done in the paths and all vacant places. If sufficient steaming troughs are at command, these and copious sprinklings will keep the atmosphere sufficiently moist for the present. Syringing overhead may be deferred for a little time, unless in the case of houses or pits heated by flues, when a gentle sprinkling with a fine syringe over the plants as the houses are closed up will be beneficial. Keep succession plants about 65° at night, with a rise of 10° to 15° by day, and on fine bright afternoons the temperature may rise to 85° for a time after closing. Keep the atmosphere moist, and on bright afternoons give the plants a slight sprinkle with a syringe with water at 85°. This greatly assists them in the formation of new roots, and in the case of large plants with only a few healthy roots it keeps them in a fresh state in the interval, and as Pines are very succulent they absorb a deal of moisture. Rooted suckers should be kept freely growing, without any check, so that when put into fruiting pots or larger sizes, they will not fruit prematurely. As many of the plants are now in flower, keep the atmosphere a little drier for a few days. This is a rule that may be applied at any season of the year. In cold, sunless weather, if stagnant moisture is allowed to accumulate on the fruit some of the pips become abortive, thereby causing deformity. Many of the plants are so far advanced as to require staking. This is a matter that should never be neglected, and should be done in due time. Ash is one of the best materials for this purpose, and the stakes should be cut and dried some time before using. When staking the plants, if they are too long, cut a piece off the upper end, and not the end that enters the soil. Put two stakes to each plant close to the sides of the pots, then take a piece of strong raffia about 3 feet long, put it over the crown, holding the two ends together towards the stakes, twist the two round each other twice, and make a knot half-way between the crown and the stake; make two more twists, and tie both ends securely to the stake. Let the ties on the stakes be 5 or 6 inches higher than the crown, so that, as the fruit rises in the plants, it is not hung or injured, but is supported in a natural, upright position. A corresponding piece of raffia should be put over the other side of the crown, and tied likewise to the other stake; this keeps the fruits in an even, vertical position during the swelling period, at the same time allowing full liberty for the fruit to expand. The Pine is not like many other fruits that require to be fertilised by the hand, or in other ways assisted to cause the fruit to set. When, however, grown under the proper conditions the flowers readily fructify, even in mid-winter, but seeds are seldom found. The temperature for these plants is not agreeable for the bees or other insects that aid in fertilising many fruits. When seed is wanted to raise new varieties the flowers must be fertilised by hand skilfully. Many fruits are, however, ill-formed by imperfect setting. *D. Wilson, Castle Hill, Devon.*

Grapes and Vineries.

THE Grapes in the earliest vinery will now be colouring fast, and must have less atmospheric moisture. As they start to colour reduce the atmospheric moisture gradually, but do not by any means let them become dry at the roots; a thorough watering with clear tepid water at a temperature of 85° as they commence to colour will be sufficient until they are ripe. Keep the night temperature 65° to 70°, with a rise of 10° by day. Admit a good supply of air on the back ventilators, and a little only on the front,

with sufficient fire-heat to keep up a circulation of warm air. Be very careful to avoid cold draughts, and do the damping down in the early part of the day, when there is plenty of air on, so that it will dry up before evening. Let the evaporating pans go dry, and go over all the corners of the house with a hair-broom to dislodge the spiders. Do not stop any lateral growths now, especially on such sorts as Foster's Seedling or Madresfield Court, which are liable to crack; but if the growth appears thick the laterals can be taken off after the Grapes are ripe, as it is only for a few weeks now that they will crack. Succession Hamburgs that are swelling their fruit must have liberal supplies of tepid manure-water, and during bright weather plenty of atmospheric moisture. If the foliage is thin let the laterals run until the trellis is covered without crowding. Keep them at a night temperature of 65°, and close early in the afternoon; and on bright days with sun-heat they may be allowed to run up to 90°, with abundance of moisture.

Hamburgs started about February 1 will now be ready for thinning; and if any extra large bunches are required a few may be tied out, or shouldered, instead of cutting out so many berries, but they never make such compact and handsome bunches as those not tied out. In thinning take out all the inside or cross berries, leaving those that point directly outwards. Those houses closed a short time ago, and growing bunches, must be disbudded and stopped three or four joints beyond the bunch, according to the room there is on the trellis. Keep them at a night temperature of 60°, with a rise of 10° by day. The latest Hamburg house must be kept as cool as possible, only closing the house when there is danger of the frost catching them, as they are this year breaking earlier than usual. Muscats that are swelling their fruit must have liberal supplies of tepid manure-water, and an abundance of atmospheric moisture. Still keep them at a night temperature of 70°, with a rise of 10° by day, and close the house at 90° with bright sunshine. Those started later will now be disbudded, and must be stopped four or five joints beyond the bunch. Muscats are better with more foliage if there is room for it without crowding. Keep them at a night temperature of 65°, steadily increasing it until it reaches 70° when they are in flower, with a rise of 10° by day. Late varieties of Grapes will now be ready for disbudding, which must be done carefully, leaving the best placed and strongest growths. Stop them at four joints beyond the bunch; and examine the border, and if dry, water thoroughly with clear tepid water. Keep them at a night temperature of 60° to 65°, with a rise of 10° by day. Admit air early in the day, and close early in the afternoon. Damp the house down several times daily, but syringing overhead can now be discontinued. For Vines colouring can now be kept with a drier atmosphere, but they will require plenty of water at the roots; and on bright mornings it is a good plan to damp the paths and borders with tepid water. While there is plenty of air on keep air on back and front ventilators night and day, and regulate it so that there will be no cold draughts, and keep the temperature 65° to 70° at night, with a rise of 10° by day. Vine eyes in pots or on turves may be potted on as they require it, keep them in a strong moist heat; and when the pots are filled with roots give weak manure-water every other day. If for planting permanent vineries I prefer them in turves, as the roots are not cramped, and the turf can be buried in the new border without any check. If they are planted with cut-backs from pots put them in a moderate heat, and let them break a few inches, and then shake them out of the pots, and after planting water with tepid water, and keep the house close, and only shade the Vines to prevent flagging until they take the new soil. *Joshua Atkins, Lockinge Gardens, Wantage.*

The Hardy Fruit Garden.

THE stormy and unsettled weather we are now experiencing is not over-favourable for the setting of the fruit blossom, and the best of protecting materials cannot prevent rapid loss of heat from the walls during such gusty nights. Extra precautions are, therefore, necessary, as the walls are being cooled and left wet by drifting showers, and are consequently placed under bad conditions for resisting the sharp morning frosts we have been having. The chances of an Apricot crop are much increased by the successional manner in which that fruit blooms, as a portion of the bloom usually thus escapes the rigours of the early season at which it opens. Apricot flowers seem to be even more irregular in their development than is their wont, and may this season be seen in all stages, from fruits as large as sparrows' eggs to opening buds. Their foliage is now developing itself

quickly, so it is to be hoped the crop is safe on walls that are afforded some protection—at least, in the southern and south-western counties. Attention cannot be too early paid to any manifestations of the presence of the Apricot maggot amongst the unfolding leaves. Destroy by pinching at present, and on a favourable change of the weather syringe freely with a weak infusion of soft-soap and quassa; or, in the event of the attack being severe, and it is found that the application of an insecticide cannot be deferred, it should be used during the earlier part of the day to allow time for the wall to become dry before night. As soon as the Peach bloom is set it will be well to examine carefully for the first traces of greenfly, which often makes rapid progress just at this time, and gives a great amount of trouble throughout the season if suffered to increase. Where thick materials have been used for protection they may be let down and damped, when a fair amount of success, proportionate to the trouble taken, will usually attend attempts at fumigation with Tobacco, which is yet, after the introduction of many novelties in insecticides, one of the best modes of destroying the whole of the aphid tribes when it can be conveniently applied. Cherry walls are now quickly becoming whitened by the profusion of their bloom, and immediate steps ought to be taken to afford some protection, if not already provided for. The principal work in this department will now consist in trying to secure a crop of fruit by giving every attention to the protecting material. Stretched and worn ties will require frequent looking after, and the tightening effects of wet and the slackening consequent upon drying allow the wind to have such power over the material used, when not well attended to, as to endanger the bloom as much by its flapping as it would by the effects of frost in the absence of protection. Complete the pruning of Cob-nuts and Filberts at once, if not yet done, keeping the bushes well open in the centre, and free from crowding in all parts. The bearing shoots of last year can be cut-back to form spurs, and the shoots for yielding this season's crop can be thinned-out where necessary, retaining those that show most bloom—which are now fully evident; and see that a sufficiency of catkins be retained at regular intervals over the bush. Any grafting yet remaining undone should be proceeded with at once, and if drying winds prevail continue to attend to the regular damping of the clay of those grafts which were put on last month. Finish planting-out Strawberries from store beds at once, if any such work remains unfinished, and see that no work is suffered to be in arrear in this department at a time when each day brings increasing business. Keep all walks clean and free from weeds, which will be a comparatively easy matter if the open winter has been utilised for turning the gravel of walks, re-coating with fresh where necessary, and in attention to their condition generally. The hoe should be used on the fruit quarters and borders upon the very first evidence of the existence of germinating weeds, which are most readily destroyed before they have developed beyond the seed leaf. *Ralph Crossling, St. Pagan's.*

The Roseery.

THE ROSE-HOUSE at REDLAND LODGE.—So much has been said and written about Roses and Rose growing, and especially respecting that most erratic of all Roses, *Marshall Niel*, that it is a pleasure to be able to record some particulars of a very fine plant grown by Mr. Vallance, gardener to J. C. Wall, Esq., Redland Lodge, Bristol. The plant covers one side of a span-roofed house, 33 feet long and 18 feet wide, and would have filled the whole house long ago had it not been deemed desirable to make safe against accident by having young plants coming forward upon the opposite side of the house. Two of the main limbs are $6\frac{1}{2}$ inches in circumference at from 2 to 3 feet from the ground. The luxuriance of the plant is not more remarkable than the number of buds which are fast approaching the opening stage—some, indeed, are just expanding. It is characteristic of this, as well as other Roses, that when the crop of buds is disproportionate to the vigour of the plant the result is a large percentage of distorted blooms, but in this case a fair equilibrium is happily maintained. The method of training, too, is all that can be desired. The shoots—some of them over 18 feet long—are fastened loosely to the wires, and the flowering shoots hang irregularly from these with grand effect. Over 3000 blooms were gathered last season, to say nothing of those that dropped in the natural order of things. The plant is budded on the common Brier, and has been planted five years. *W. H.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, April 11	{ Royal Horticultural Society: Meeting of Fruit and Floral Committee, at 11.30; Scientific Committee, at 1.30.
WEDNESDAY, April 12	{ Sale of Second Portion of Mr Yates' Or- chids, at Stevens' Rooms.
THURSDAY, April 13	{ Sale of Imported Orchids, at Stevens' Rooms.
SATURDAY, April 14	{ Sale of Stove, Greenhouse, and Hardy Plants, at Stevens' Rooms.

THE establishment of a FOREST SCHOOL in this country, to the necessity for which we have often called attention, will receive a fresh impetus from the valuable report printed in the current number of the *Journal of Forestry*, from the pen of M. BOFFE. It appears that the gentleman just named, who is connected with the French School of Forestry at Nancy, recently paid a visit to several of our British forests in company with Colonel PEARSON. What they saw and what they did in their visit of inspection from the Highlands to the New Forest, and from Windsor to the Forest of Dean, is concisely and graphically told in the article before us. After a few brief paragraphs devoted to the history of the Scottish forests, which are amply worth reading, we come to the year 1870, when the work of replanting the vast areas left desolate by neglect and the ravages committed by sheep "seems to have recommenced with increased ardour, so that on all sides may be seen young plantations vigorously striving to fill up the gap which separates them from those of half a century's standing." Adverting to the Highland district north of Perth, and after making allowance for unproductive areas, M. BOFFE calculates that there will still remain 5,000,000 acres capable of furnishing valuable timber-forests, and affording a vast field for enterprise and capital. Thanks to the punctuality and precision "so thoroughly characteristic of Englishmen," Mr. Inspector BOFFE and his companions were enabled to thoroughly inspect more than 100,000 acres of every description of forest under every-
varying physical and geological conditions.

What old SAM JOHNSON, who playfully doubted whether Scotland produced (in his time) timber enough to make him a stout walking-stick, would have said to these French forest officials we can only barely imagine. Suffice it for us to say, that they were struck in Scotland with the magnificent specimens of Oak, Maple, Lime, Elm, Ash, and Beech, which, by their vigour and the rich colouring of their foliage, bore testimony to the favourable conditions of soil and climate under which they grew. They were, they tell us, struck with admiration at beholding the colossal trees forming the avenues at Scone, Dunkeld, Blair Athol, and Darnaway, and the Oak forest of 400 acres planted sixty years ago by the venerable father of Scotch forestry, Mr. McCORQUODALE. In selecting the Scotch Fir as the tree to be cultivated before all others, the promoters of forest plantation have not only insured the success of their operations, but have traced out the best line of action for their successors. The introduction of the Larch is also spoken of with sympathetic admiration. The reporter further counsels the planting on a larger scale of the Beech, either as a substitute for the Birch, or, better still, mixed with it. For the peat mosses the introduction of *Pinus montana* (Mugho) is also recommended. The different conditions under which Scotch forests are managed, as compared with those on the Continent, attracted the attention of the Inspector. Everywhere, he says, he found the forests fenced in on all sides with walls and hedges, these costly enclosures being erected, not for the purpose of keeping out the cattle and the deer, but for the purpose of keeping them in; "it appeared to us like shutting up the wolf in the sheepfold." They were also struck "by the monotonous regularity in height and age of the trees, unmistakable signs of their artificial origin and want of

methodical management. The forest here left to its own devices continues growing just as the hand of man has planted it; the undergrowth is constantly grazed down by the sheep and cattle, and Nature, in spite of the immense resources at her disposal, is quite powerless to modify the work of the planter or to repair the errors committed by woodcutters. When, under such circumstances, the time arrives for the trees to be cut down, or should they be uprooted by a hurricane, the forest disappears in its entirety owing to the total want of young growth which is necessary as a link between the old forest and the new one which ought to be created."

After adverting to some lamentable illustrations of the want of system, the reporter alludes to two forests near Grantown in Strathspey, the other at Beaulieu, where nothing has been neglected which even the most critical forester could desire. The gradation of the trees was complete, and the reservation of specially vigorous trees of known pedigree duly carried out. The *modus operandi* here pursued consists simply in the exclusion of the sheep and deer, in the judicious thinning out of the growing crop, and in the removal of the mature seed-bearing trees by successive fellings as the young forest grows up and acquires more vigour. . . . If every year certain positions of the forest best capable of supporting it were marked out for grazing the quality of the pasturage would be greatly improved, and the heather would quickly disappear under the cover."

But although the regeneration of a forest will be assured by the exercise of a discreet control over the grazing, "something more must be done if it be desired to turn the land to the best possible account. It is therefore a matter of regret that nothing has yet been done to place forest management in Scotland on a sound economic basis. The productive power of the soil and of the climate have been made use of by able and intelligent planters, who have thereby enabled Nature herself to accumulate a considerable store of timber; but all this wealth is exposed to the carelessness of some and to the ignorance of others, until the hand of a forester manages it properly, and places it on the only sound economic principle of all agricultural and forest property—a constant annual revenue and a constant improvement in production." M. BOFFE is careful to hold foresters exempt from the responsibility of the present state of affairs, as they are powerless to effect improvements until the landowners can be brought to appreciate the manifold advantages to be derived from a regular and methodical management. A parting word of advice is given to forest owners, not to allow their forests to be overworked—a temptation to which they are now exposed when ordinary Fir timber fetches 8*s* per cubic foot, and Larch nearly double that amount.

The proper system of management is detailed in the following manner:—"Let the owner of a forest, after having made a careful and detailed inspection of it, divide it off into blocks or compartments so arranged that they shall be uniform as regards conditions of soil and planting, and then proceed to count and measure all the trees of 3 feet girth and upwards, classing them into categories according to their diameter. He should then open a debit and credit account for each compartment, placing on the debit side the actual volume of the standing crop, and on the credit side the volume of timber removed at each successive felling. This register should always be consulted before undertaking any forest operation, and when the annual fellings fall due it will show which compartment can best support the withdrawal of timber, and which require to be left untouched. Moreover, the balance-sheet will render an exact account, favourable or otherwise, of the condition of the

forest. Ten years of such systematic treatment would form in itself the basis of a regular forest working plan, and the doctor's prescription would no longer frighten the patient with its long words."

We defer for the present further notice of M. BOFFE'S comments on the Royal Forests of Windsor, the New Forest, and the Forest of Dean, to which we shall advert on a future occasion.

On their return from their tour of inspection the visitors were requested to report to the India Office and formulate their opinions as to the desirability and practicability of establishing one or more forest schools in Britain. On both points the Inspector gives a decided affirmative response, considering the establishment of Forest Schools a matter of primary importance, not only as regards Great Britain, but also as regards India and the colonies. A plantation, it is pointed out, cannot afford all the requisite facilities, so that study in a natural forest properly managed is an essential. The forest, to be used as a training school, must be absolutely under the control of the officers of the school. This can only be done in a State forest, which in case of need should be purchased or leased for the purpose. It is recommended that professorships of forest economy should be founded both in England and in Scotland, Cooper's Hill being advised as a suitable locality in the one case—Edinburgh in the other.

We reserve for another occasion the mention of the recommendation as to the course to be followed by the professors and as to their duties; we have said enough to show that the report of M. BOFFE is worthy of the fullest consideration, not only by State officials, but also by our landed proprietors. The report is clear, concise, and to the point. Practical readers may possibly object to some of the details, but they cannot fail to appreciate the thoroughly lucid, business-like character of the report, agreeable in style though free from verbiage, practical, and to the point, though written in a style which will prove attractive even to the general reader.

—WORK.—It is a curious result of the mild winter we have had that work should be apparently somewhat slack for the season, which is invariably a busy one. In towns large bodies of labouring men may be seen standing idle and waiting work, whilst in the rural districts, amongst the market gardens and fields, the complaint of the comparative slackness of labour is as evident. The reason is to be found in the open nature of the winter, which gave no check to work, so that it has gone on almost uninterruptedly since the autumn, and has thus been greatly accelerated. When, as in the preceding winter, a long interregnum of frost and snow locked up the soil from willing hands, work is thrown back for a month or longer, and extra help is needed in the spring to make up for the lost time. Garden and farm work has never been more forward than now, and the early running away to bloom of all green crops enables the land to be re-cropped earlier, and with more than the usual deliberation. There is no complaint as to slackness of work from the regular labourer; it is rather the workman on tramp who finds that the mild winter has put him on a level with Othello—his occupation gone. We shall some day have to face the solution of this great tramp problem, for it is growing a serious one, and is perhaps an outcome of that divorce of the labourer from the soil in rural districts. Farms falling into the hands of the owner are either left neglected or worked with one-half the usual labour, and thus some of the old hands are turned adrift to shift for themselves. They, as so many thousands have done in vain before, resolve to try their luck in the great towns, and getting no work, are, by force of the circumstances in which they are placed, soon converted into shiftless, loafing tramps, who at last get to think that a miserable existence by tramping from one union house to another and eking out a bare subsistence is better than absolute starvation. If our rural labourers had some such tie to the soil as real interest in it or ownership gives, we should not find them

so readily lapsing into the degrading position of loafing tramps and vagabonds.

— THE AURICULA SHOW AT SOUTH KENSINGTON.—Mr. SHIRLEY HIBBERD will give a lecture on the history of the Auricula in connection with the exhibition by the National Auricula Society at South Kensington, on April 25. The arrangements will be as on former occasions, the lecture to be given in the midst of the flowers in the conservatory at 3 P.M.

— THE NEW DOUBLE PINK ROUVARDIA.—This charming plant has already been referred to, and will shortly be offered for sale by Messrs. JAMES

interest of a less satisfactory kind, as showing that Greece is no more free from insect and fungus pests than other lands. The numerous pamphlets before us deal with the Phylloxera, the Anthracnose (*Phoma uvivicola*) of the Vine, its nature and treatment, scale insects, and various other plant diseases.

— THE WEATHER OF 1881.—Mr. EDWARD MAWLEY, whose careful diligence we have before had occasion to comment upon, has published a series of meteorological tables, forming a record of the climatal conditions observed throughout the year near London. The record is absolute and also comparative with reference to an average year, so that it will be very serviceable for reference, and with its two pre-

south-west wall of the Castle. The flowers are quite up to their normal size as seen under pot cultivation, and quite as vivid in colour as if they had the protection of the most modern glass structure. The plant is trained loosely to the wall, and the profusion of its flowers, nestling among its green leaves and surrounded by the beautiful verdure which is characteristic of the climate, and which Nature in her kindness affords to Luscombe in a remarkable degree, renders it at once an object of striking beauty at a season when one least expects to see a display of choice flowers out-of-doors.

— MAGNOLIA CONFUCIA.—To do full justice by way of description to a large tree in full flower of

FIG. 75.—CRAIG-Y-NOS CASTLE, BRECON: THE RESIDENCE OF MADAME ADELINA PATIL. (SEE P. 464.)

CARTER & Co. It will no doubt make a handsome addition to this beautiful tribe of plants. It is described as follows:—"A sport from the double white; is very constant and beautiful, and in every way as desirable as its parent."

— BOTANY FOR BEGINNERS.—The second Dutch edition of this little book, originally published in these columns, has been published lately, with additions from the works of THOMAS and others.

— ΕΚΘΕΣΙΣ ΠΡΟΣ ΦΥΛΛΟΞΗΡΑΣ (a treatise on the Phylloxera).—It is not often we have to cite modern Greek publications in this journal, but the receipt of a whole packet of papers from M. GENNAIUS is at once interesting as a proof of scientific activity in a kingdom which has not hitherto greatly contributed to modern knowledge, and it possesses

decessors will form a trustworthy record of three years as extraordinary in their meteorological features as any three consecutive years in the memory of the oldest inhabitant. As few things pass more quickly from the unaided memory than weather statistics, the value of such records is the more evident. This convenient little publication may be had for a small sum from STANFORD, Charing Cross.

— HOVA GLOBULOSA.—We inadvertently omitted to mention in our report of the Royal Botanic Society's show, at p. 441, that the Cranston Nursery and Seed Company, Hereford, were awarded a Botanical Certificate of Merit for this plant.

— CAMELLIA IMERICATA OUT-OF-DOORS.—This well-known favourite variety is now in full beauty at Luscombe Castle, South Devon, upon the

this charming plant, one might use the choicest words which our language affords, and yet fail to convey with adequate force the true beauty and usefulness of the plant. A very large tree has been in flower for some time past in the American garden at Luscombe Castle, South Devon, and is just now at its very best. Those who have a hankering after the white *Lapageria* will find a strong rival in this lovely flower for decorating glasses or large vases of any kind, and it has this advantage over the *Lapageria*, that it emits the sweetest fragrance while its colour is the purest white. The blossoms are best gathered when about half open, and the effect they produce in contrast with scarlet *Rhododendrons* either out-of-doors or in a cut state, is transcendently lovely.

— CAMELLIAS FLOWERING IN YORKSHIRE.—Mr. ARTHUR BOOTY, Rose Villa Nursery, High

Harrogate, sends us a bloom of a striped *Camellia* cut from a bush, 4 feet high, which has stood the Harrogate winter without any protection.

— **THE FLORE DES SERRES.**—The seventh, eighth, and ninth parts of the twenty-third volume have just been issued. They contain numerous coloured plates, which we shall catalogue in our register of plant portraits, and a variety of miscellaneous articles, some of them having a special interest, as being posthumous publications of M. DECAISNE—one in particular, on the wild Pear. In the wild state the fruit has always the form of a depressed sphere, or of a top (pyriform); the colour is green, and never purplish; all become brown in ripening (blet), and their flesh, at first hard and astringent, softens, and assumes a vinous odour. Colour, form, size, flavour, aroma, season of ripening, all these are modified by cultivation. M. DECAISNE thinks that the brilliant coloration of some Pears cannot be attributed to intense light, inasmuch as in the sunny season of 1865 the Pears were not brightly coloured, but the reverse, while many of the varieties of the South of France are not more brightly coloured than those in the North. The cultivated Pears are all reduced to one species, *P. communis*, together with one variety, *P. communis subnuda*, characterised by rounded leaves, greyish above, pubescent beneath, and with the fruits borne on long stalks. This, M. DECAISNE thinks, may be a hybrid between *P. communis* and *P. parviflora*. M. PLANCHON'S article on the so-called Indian *Azalea* is reproduced from the *Revue Horticole* of 1854, without having been submitted to the author for revision—a circumstance the more to be regretted as, no doubt, after the labour of MAXIMOWICZ, M. PLANCHON might see cause to modify his views. Almost certainly he would not include the so-called *Azalea mollis*, then unknown to him except by name among the "Indian *Azaleas*," which are *Rhododendrons* of the *Tasica* sections.

— **PRIMULA MARGINATA.**—Amongst the numerous plants now flowering on the rockwork in the York Nurseries, this Italian species is very pleasing, and even gay. Its large trusses of bluish-lilac flowers contrast well with the silvery glaucous foliage of the plant.

— **CONVALLARIA POLYCONATUM** (SOLOMON'S SEAL).—This charming plant is used with good effect for the embellishment of the large conservatory at Hentez, near Bristol, by Mr. FARMER, gardener to S. DEKHAM, Esq., who also finds it a most valuable plant for general purposes of furnishing. It is a plant that can hardly be misplaced by the greatest tyro, and its cultivation is so simple that any one may undertake to grow it. Of course, it has to be forced to have it in flower at this season, and it has no equal among hardy plants with regard to giving effect. It can be obtained through any nurseryman at a cost that is not worth naming, and those who now grow a dozen or so of plants would find it an advantage to grow it in larger numbers. It is quite as useful out-of-doors as it is for forcing, and would make many a woodland walk that is now scantily furnished with living plants bright and cheerful during its season of flowering. There are scores of hardy plants—useful in their way—that one tires of reading about that will not bear comparison with it in the same breath.

— **A NOTABLE SIEPHANOTIS.**—So many questions are asked from time to time relative to the simplest method of cultivating this favourite sweet-scented flower that no plea need be offered for recording what may be called extraordinary results. The plant which is the subject of this notice covers the whole roof of an ordinary sized plant-stove in the garden of Mrs. MILLER, Brently House, Westbury, Bristol, and is under the charge of Mr. GIBSON, whose success in plant growing does him credit. The remarkable part of the history of this plant is that it is growing in a pot no larger than 11 inches in diameter. It is top-dressed with loam, and the top-dressing is raised several inches above the rim of the pot, "cup" fashion, in order to be able to supply the roots with water. Myriads of roots are protruding through the top-dressing. Some of the shoots are 25 feet in length, and as an instance of the wonderful floriferousness of the plant it may be mentioned that two trusses of flowers are produced at most of the joints, and as many as thirteen pipes may be counted to many of the trusses. Cultivators who may have found it difficult to obtain such marvellous results

would do well to inquire whether in addition to being over-generous as to treatment they do not also possess the wrong variety. With Mr. GIBSON the plant flowers at all stages; even in the cutting pots young plants are furnished with from one to two trusses of flowers. Admitting that much of this success may be due to cultural treatment and judicious restriction of the roots, it is still more probable that the variety is, like the *Elvaston* one, more floriferous than that commonly cultivated.

— **MUSK.**—The other day when a report got abroad that the gardens attached to Chelsea Hospital—so dear to the old pensioners and the Chelsea public—were to be closed, the matter evoked very considerable feeling, though perhaps there was no substantial foundation for it. But all who have been in years past favoured in a visit to these gardens cannot fail to have noticed the numerous patches of Musk grown by the old pensioners, and which they retail out in small clumps at the proper season to the intense satisfaction of the public and the old soldiers' profit. Were there no other indications existing, this one would suffice to show that the love for the simple and singularly unpretentious, yet sweetly perfumed perennial *Minimus*, is very strong, and is perhaps more evidenced in towns and cities than in rural districts. In the former the Musk is just one of those kindly plants that will thrive and flower admirably. Plants that are thus kindly under the blighting atmospheric conditions that exist in crowded centres are indeed few, and that they are thus rare renders the sentiment that is lavished upon them reasonable and natural. It was a natural result of this generosity that the now well-known HARRISON'S Musk should also become a favourite, though it does materially lack that rich perfume which so distinctly marks the old kind. But perhaps some of the popularity which is attached to the latter Musk is due to the fact that it presents almost the only variation from the normal type yet put into commerce. The old Musk is not a fertile breeder in the hands of the hybridist, hence the sterility that has marked the efforts of that enterprising section of horticulturists. Mr. A. CLAPHAM, now of Kensington, is perhaps the most successful of all in securing results, though his great aim, to secure a red-flowered Musk, has not met with the entire success he deserves. Having first obtained a variety that produces flowers of a pale lemon-yellow, he has now secured not only a robust kind that produces clear orange-yellow flowers, but one of less robust habit that carries reddish-buff flowers, of good size and form. These kinds perhaps mark the way to something yet more striking and novel.

— **SPRING SHOW OF THE PARIS HORTICULTURAL SOCIETY.**—This meeting took place in the rooms of the Society, 84, Rue de Grenelle, Paris. It was opened on March 30, and closed on Sunday night, April 2. The exhibitors were not very numerous, the Versailles nurserymen being the only great exhibitors, with M. LÉVÊQUE, the well known Rose grower. In the big meeting-room were nicely arranged some groups of *Azaleas*, *Camellias*, *Cinerarias*, and *Roses* in pots. In the several committee-rooms were staged some more *Azaleas*, a collection of *Orchids* from M. LUDDEMANN, and another from MM. THIBAUT & KEFFLEER. The arrangements appeared very good. MM. LÉVÊQUE had an enormous lot of *Roses* in pots, nicely flowered, not for competition; also some good *Camellias* in flower. *Pipl-me d'Honneur*. M. LUDDEMANN, the *Orchid* lover, of 20, Boulevard d'Italie, Paris, had a group of *Orchids*, also a few *Bromeliads*, *Orgiesia tillandsioides*, *Vriisia splendens*, *brachystachys*, and *Mazinei*. A Gold Medal was awarded. We are glad to see that French nurserymen are beginning to exhibit *Orchids*, when will French amateurs follow? It is very seldom that they exhibit at all. MM. THIBAUT & KEFFLEER, the nurserymen, of *Seaux*, exhibited a collection not for competition, their most remarkable plant being an *Odontoglossum vexillarium*, with four flower-spikes; flowers good, and a very healthy plant. M. ROYER fils, nurseryman, Versailles, showed some very good *Azaleas* in different groups, according to the sizes, and was awarded a Silver-gilt Medal. M. JACQUIN had a Silver Medal for a good lot of well-flowered *Mignonette*; and M. FORGEOT, 8, Quai de la Megisserie, a Silver-gilt Medal for *Hyacinths* in pots and in cut flowers; M. TRUFFAUT, 40, Rue des Chantiers, Versailles, received a Silver-gilt Medal for a lot of *Cyclamens* in pots, something after the Eng-

lish style of plants; the same exhibitor received also a Gold Medal for a fine group of *Azaleas* well flowered in best varieties. M. MILLET showed *Violets* of sorts, seedlings of his own and others. M. PAILLET, of *Seaux*, contributed a group of *Magnolia stellata*, very well flowered; and *Viola purpurea*, white, double, &c., and received a Silver Medal. M. LECARON, 20, Quai de la Megisserie, had a Silver Medal for *Calceolaria*, *Cineraria*, &c.; and to M. MOSER, nurseryman, of Versailles, who had a large lot of *Camellias*, well bloomed, a Gold Medal was awarded. MM. VILMORIN were awarded a Silver-gilt Medal for a group of *Cinerarias*, very good; also a Silver Medal for a white *Cineraria* and *Hyacinths*. Fruits and vegetables were sparingly represented, and of new plants we only noticed an *Anaryllis*, red, striped with white, exhibited by M. TRUFFAUT; a *Coleus*, dark red fringed green, and a few spots pale pink, from Messrs. THIBAUT & KEFFLEER; *Rhododendron Souvenir du Prince Imperial*, a free blooming variety, dark red, from M. ROYER, of Versailles; and the new bedding plant, *Gynura aurantiaca*, from the *Compagnie Continentale d'Horticulture*, we do not think this will ever take the place of *Coleus Verschaffelii*, speaking of course from an effective point of view—it has not the brilliant colours of these old plants. The great show of the season of this Society will take place in the Champs Elysées, from May 23 to 29, inclusive.

— **ARISTOLON SELLOWIANUM VARIEGATUM.**—A very interesting specimen of this excellent bedding variety has lately come under notice at Coombe Bank, Sevenoaks, the seat of W. SPOTTISWOODE, Esq., President of the Royal Society, which deserves a word of praise. The plant is growing in the plant-stove, and, owing to the conditions under which it is grown, the markings of the leaves present the most delicate tints of green and gold, canary-yellow, and pure white. Some of the white blotches change insensibly into the most delicate yellow tinted with green spots. A more suitable ornament for a sitting-room cannot well be conceived. When it is remembered what a striking plant this is in the subtropical garden, and the readiness with which it may be propagated, it will be seen what a useful subject it is, when grown in suitable sizes, for all modern purposes of decoration.

— **PYRUS MAULE.**—This charming spring-flowering shrub, originally described and figured in these columns, was exhibited in fine form at the late show of the Bristol Horticultural Society by Messrs. MAULE & SON, nurserymen, of that city, where its rich orange-scarlet blossoms contrasted beautifully with *Rhododendron multiflorum* and white *Azaleas*. The plant was most conspicuous in a group of plants set up for effect; it is indeed a plant that will attract attention anywhere, but it is especially adapted at this season of the year for grouping with other plants where a distinct effect produced in a natural way is the chief aim of the cultivator. Plants that produce such a rich display with a minimum of labour should find a home in every amateur's garden in the kingdom.

— **THE HYACINTH EXHIBITION AT THE EXETER NURSERY**, which has now become an annual thing, there being no other spring show in the city, this season formed a great centre of attraction to the flower-loving section of the populace, who patronised it largely. This was the fifth annual display, and far exceeded any of its predecessors, showing that the efforts of the DR. WOODMAN (the head of the firm) to promote the high-class culture of this popular spring flower have been crowned with success. The privilege of exhibiting for competition was confined to customers of the firm; the valuable prizes offered brought out strong competition. The 1st prize was awarded to Mr. COLE, gr. to J. LAWLESS, Esq., of Topsham Road, Exeter, with a very superior collection, comprising *La Franchise*, white; *La Nuit*, black; *Agnes*, pink; *Mimosa*, purple; *Grande Vedette*, pure white; *Robert Steiger*, a lively red; *Mont Blanc*, pure white; *Prince de Saxe Weimar*, double blue; and *La Tour d'Auvergne*, double white. The 2d prize was awarded to Mr. SPARKS, gr. to W. T. WALDY, Esq., Hewden Court, Tiverton, with two very nice blooms, conspicuous among them being *Ornement de La Nature*, rose, striped pink; *Marie*, blue; *Mimosa*; *Vulcan*, blue; and *Queen Victoria*. The 3d prize went to Mr. BAKER, gr. to T. ROWE, Esq., Lafonda, Exeter; equal 3d to Mr. STEVENS, Alphington. The collec-

tions sent by Mr. Hart, Alpbington, STAFFORD GREEN, Esq., HEWITT, and Captain HALFORD THOMPSON, were commended; several other exhibitors competed. Additional collections were staged by many of the exhibitors, not for competition. Messrs. LUCOME, PISCHE & Co. staged a great many themselves, of superior merit. The plants were staged in their long span-roofed show-house, backed up on each side with productions from the nursery, such as white Arums, Acacias, Deutzias, &c. with Palms and tree Ferns skillfully arranged; the same gave a charming finish and effect to the display. The whole of the houses in the nursery were thrown open to the public, who were admitted free—these being principally their large and noted Camellia-houses, one filled entirely with Cinerarias—a fine display, another full of Anthurium Scherzerianum in full bloom; some hundreds of flowers, of varied shades of colour, among them a seedling of superior merit, of a deep crimson-scarlet. The Orchid-houses contained many specimens in bloom, such as *Acinetia Humboldtii*, *Phaius giganteus*, *Phalaenopsis grandiflora*, &c. With the many other houses, containing much to please and interest, a very pleasant afternoon could be spent, thanks to Dr. WOODMAN and his employees, who are to be complimented on the marked improvement of the nursery as seen from year to year.

— **HIBISCUS ROSA SINENSIS**.—A flower of a superb variety that we have lately examined is so remarkable in its conformation that its peculiarities are worthy of being placed on record. All goes on as correctly as should be the case with a properly conducted *Hibiscus* till after the corolline whorl is reached; then the flower breaks out into the wildest extravagance, so that it is difficult to reduce the tangled mass of petals to anything like order. In the ordinary course of things there should be within the petals a tube, bearing at its upper part an agglomeration of anthers, and forming the column or tube of stamens so characteristic of well conducted Malvaceae. Within and at the bottom of this tube of united stamens is, or should be, the ovary whose slender style traverses the tube and breaks up above its edge into five branches, each tipped with a knob-like stigma. In the flower before us we have a very different arrangement. Instead of the staminal tube we have six solid branches or axes clothed with petals of all sizes and shapes, and each bearing at the top a few stamens surrounding the base of a small but perfectly formed ovary, whose styles and stigmas, however, though present, are but small. It would therefore seem as if the main axis of the flower, after throwing off sepals and petals as usual, suddenly branched into five or six divisions, each provided with an irregular number of petals, and terminated by an ovary. It is difficult to suppose any real transformation here; but if such a phenomenon be invoked, then the five or six branches of the flower must be stamens, but stamens must be very much indeed to bear complete ovaries at their tips, though we are far from denying the possibility of such an occurrence.

— **TESTIMONIAL TO MR. W. MUIR**.—Mr. WILLIAM MUIR, who for nearly seventeen years occupied the post of head gardener to the late Sir PHILIP DE MALPAS GREY EGERTON, of Oulton Park, near Little Budworth, Cheshire, has received the more important appointment of head gardener to the Earl of HOPETOUN, of Hopetoun House, near Edinburgh, and his departure from Oulton is deeply regretted by a large circle of friends. Last week he was the recipient of a "keepsake," which testified in a most unmistakable manner to his popularity in the neighbourhood in which he has so long resided, consisting as it did of a purse containing fifty sovereigns, together with a handsome black marble timepiece, upon which was a gold plate bearing the following inscription:—"Presented, together with a purse of money, to Mr. WILLIAM MUIR, by friends, as a mark of respect and esteem, on his leaving Oulton Park, March, 1882." Mr. MUIR was also presented with a very handsome pipe, tobacco-box, and an illuminated address by the gardeners and farm workmen of the Oulton estate. The address was surmounted with the arms of Sir PHILIP EGERTON and the Earl of LONDONDERRY, with crest and motto of the first, and enclosed within a rich border of cinque-cento design upon a ground of gold filagree work.

— **PERIODIC PHENOMENA OF PLANTS**.—Dr. H. HOFFMANN and Dr. EGON IHNE, of Giessen, who are engaged in preparing a map of the plant-phenology of Europe, are desirous of obtaining accurate dates of the flowering and fruiting of the under-mentioned plants in this country, from as many localities as possible. The observations are to be made (on isolated trees, not protected by walls, nor trained in espalier) during the present year, or from previous years, if not already published. An example of the work intended may be seen in a map published in PETERMANN'S *Geographische Mittheilungen* for January, 1881, entitled "Vergleichende phenologische Karte von Mittel-Europa." The dates are the average observed at Giessen:—

A. First Flowers Open.

1. Ribes rubrum. Red Currant	April 14
2. Prunus avium. Wild Cherry	" 19
3. P. spinosa. Sloe, or Blackthorn	" 20
4. P. Padus. Bird Cherry	" 24
6. Pyrus communs. Pear	" 23
*7. Malus. Apple	" 25
*8. Syringa vulgaris. Lilac	May 4
9. Lonicera tatarica. Tartarian Honeysuckle	" 5
*10. Narcissus. Pleasant-scented Narcissus	" 5
*11. Asculus Hippocastanum. Horse Chestnut	" 5
13. Crataegus oxyacantha. Hawthorn	" 9
13. Cytisus Laburnum. Laburnum	" 15
14. Sarcodanthus vulgaris. Broom	" 14
15. Cydonia vulgaris. Quince	April 16
16. Sorbus aucuparia. Mountain Ash, or Rowan	" 17
*17. Samolus nigra. Elder	" 21
18. Scutella cretica. Rye	" 28
19. Atropa Belladonna. Deadly Nightshade	" 29
20. Vitis vulpina. Vine	June 12
21. Thia grandifolia. Ehrh. Line	" 12
22. Lilium candidum. White Lily	July 1

B. First Fruit Ripe.

23. Ribes rubrum. Red Currant	June 21
24. Lonicera tatarica. Tartarian Honeysuckle	July 1
25. Sorbus aucuparia. Mountain Ash, or Rowan	" 30
26. Atropa Belladonna. Deadly Nightshade	Aug. 2
*17. Samolus nigra. Elder	" 11
*28. Asculus hippocastanum. Horse Chestnut	Sept. 17

Particular attention is requested to the species indicated by an asterisk. Communications to be addressed to Dr. IHNE, Giessen, Germany.

— **THE GENERAL HORTICULTURAL COMPANY (JOHN WILLS), LIMITED**.—This case came before Mr. Justice FRY on Tuesday. The Company was represented to be doing a large business, and it was stated that the shareholders and the bulk of the creditors desired the Company to continue its business on the idea that it would be ultimately successful. The petitioner did not object, and accordingly, notwithstanding the opposition of certain creditors, his Lordship, considering it to be in the interest of all parties, directed the petition to stand over for three months, and in the meantime continued two provisional liquidators, Messrs. STAGG and SMITH, for the purpose of carrying on the business of the Company.

— **THE WEATHER**.—General remarks on the temperature, rainfall, and duration of bright sunshine, for agricultural and sanitary purposes, during the week ending April 3, issued by the Meteorological Office, London:—The weather has been cloudy or dull in all places with rather frequent, but slight, falls of rain. A sharp thunderstorm passed over central England on the 2d. The temperature has been much higher than that of last week, and was above the mean in all districts, the excess over southern and eastern England being as much as 6°. The highest reading recorded (64°) was registered at Southampton on the 3d, while the lowest reading (29°) occurred at Hillington on March 31. The rainfall has been rather more than the mean over Scotland, in England, S.W., and "Ireland, S.," and equal to it in "England, S.W.," but in all other districts the fall was a little less than the mean value. Bright sunshine shows a further decrease, the percentages varying from 8 in "Scotland, E.," and 17 in "England, N.W.," to 38 in "England, S.," and 39 in the "Midland Counties." Depressions observed: During the first few days the barometer was highest over the southern part of our area, and depressions travelled in an easterly direction over our northern coasts and Scandinavia. The prevailing current was consequently south-westerly or westerly, and generally moderate or fresh in force. On the 31st, however, there were indications of a change in the distribution of pressure, and from April 1 until the close of the period the mercury was highest over Scandinavia and lowest to the south-westward of our islands, so that the wind became easterly and south-easterly in direction, and moderate to strong in force.

— **GARDENING APPOINTMENTS**.—Mr. M. GLEESON, Foreman to Mr. ELPHINSTONE, The Gardens, Shipley Hall, Derby, has been engaged to succeed Mr. MILLER, as Gardener to the Duke of NEWCASTLE, at Clumber.

LIST OF GARDEN ORCHIDS.

- DENDROBIUM.
- (Continued from p. 397.)
124. D. INFUNDIBULUM, Lindl., *Journ. Linn. Soc.*, iii., p. 16; ex Bateman, *Gard. Chron.*, 1862, p. 1194; *Bot. Mag.*, t. 544; *Ill. Hort.*, n.s., t. 172; *Gard. Chron.*, 1864, p. 269; n.s., ii., p. 167; *D. mouli-mensis*, HORT., n.s., introduced by the Rev. Mr. Parish for Messrs. Low about 1865. A handsome white-flowered Dendrobium, which I should regard as a narrow-leaved variety of *D. formosum*. I doubt its being Lindley's *D. infundibulum*, as this is described as having large, round, lateral lobes to the labellum.
 125. D. INTERMEDIUM, Teijsm. et Binnend, *Nederl. Kruidb. Arch.*, iii., p. 399, reprint, p. 6.—Java. Buitenzorg Botanic Garden, 1866. Inconspicuous.
 126. D. (NIGRO-HIRSUTA) JAMESIANUM, Rehb. f., *Gard. Chron.*, 1869, p. 554; *Jardin et Potager*, 1869, p. 187, with a woodcut.—Birma. Discovered and introduced by Colonel Benson, and acquired by Messrs. Veitch. Described as a splendid species, allied to *D. infundibulum*, having large snow-white flowers, with a cinnabar-red lip. Dedicated to the late J. James, Esq., Kew.
 - D. JAPONICUM, Lindl. = *D. noniflorum*.
 127. D. JAVANICUM, Lindl.; Miquel, *Fl. Nederl. Ind.*, iii., p. 644; *D. sarcoctoma*, Lindl., *Gen. and Sp. Orch.*, p. 80; *Sarcoctoma javanicum*, Blume, *Bot. Burck.*, p. 154, t. 15, f. 15.—Java. Discovered in the garden of Lady Louisa Ashburton. Flowers small, cinnabar-red, with a dark purple labellum.
 128. D. (BOLBOPHILA) JENKINSII, Wallich, *Bot. Reg.*, 1839, t. 37; Warner, *Sel. Orch.*, ser. 2, t. 28.—Gualpara, Assam, India. Discovered by Captain Jenkins; introduced into this country by Dr. Wallich, and flowered by Messrs. Loddiges in 1838. A dwarf ornamental species. Flowers wholly yellow.
 129. D. (NIGRO-HIRSUTA) JERDONIANUM, Wright, *lc. Pl. Ind. Or.*, v., t. 1644; *Gard. Chron.*, 1868, p. 865; *D. villosulum*, Wallich, = Neighley Mountains, Sikkim, India. Discovered in the garden of Lady Louisa Ashburton. Flowers small, cinnabar-red, with a dark purple labellum.
 130. D. JOHANNIS, Rehb. f., *Gard. Chron.*, 1865, p. 890; n.s., ix., p. 163; *Bot. Mag.*, t. 5540.—North Australia. Discovered and introduced by John Gould Veitch, Messrs. J. and F. Anderson, but it has narrower leaves and smaller fragrant flowers, with chocolate-brown sepals and petals, and a yellow labellum with crimson pencillings.
 131. D. JUNCEUM, Lindl., *Bot. Beech.*, 1842, Misc., n. 11; *Gard. Chron.*, 1873, p. 261.—Singapore. Imported by Messrs. Loddiges, with whom it flowered in 1842. "Leaves terete; flowers medium size, green, with faint purple veins."
 132. D. (DENDROBIEUM) KINGIANUM, Bidwill ex Lindl., *Bot. Beech.*, 1844, Misc., n. 18; 1845, t. 61; Paxt., *Mag. Bot.*, iii., p. 97, with a coloured figure; *Bot. Mag.*, t. 4527; Lemaire, *Jard. Fleur.*, t. 143 (copied from the *Bot. Mag.*).—Queensland and New South Wales, Australia. Originally collected and introduced alive into this country by Mr. Bidwill in 1842. Flowers small, in racemes from the apex of the commonly two-leaved stems, violet-purple. Hort. Kew.
 133. D. KOHLEMEYERIANUM, Teysm. et Binnend ex Miquel, *Choix de Pl. Jard. Buitenzorg*, t. 24, fig. 1.—Java. Small, narrow flowers.
 - D. KUHLII = *D. thyrsoides*.
 134. D. LASIOGLOSSUM, Rehb. f., *Gard. Chron.*, 1868, p. 682; 1869, p. 277; 1870, p. 695; *Bot. Mag.*, t. 5245.—Birma. Discovered by Colonel Benson, and by him communicated to Messrs. Veitch, with whom it flowered in 1862. Allied to *D. areum*, but the flowers are wholly white, with the exception of some reddish streaks on the lateral lobes of the labellum, and the tuft of yellow hairs on the central lobe. A fine species.
 135. D. (AFORUM) LEONIS, Lindl. ex Rehb. f., *Walp. Ann.*, vi., p. 280; *Aforum Leonis*, Lindl., *Bot. Reg.*, 1840, Misc., n. 126; *A. indivium*, Lindl., *Gen. and Sp. Orch.*, p. 70, nec Blume.—Singapore. Introduced by Mr. Cunningham, and flowered by Messrs. Loddiges to the genus.
 136. D. (EUPHORBIOIDUM) LEUCOCHROUM, Rehb. f., *Gard. Chron.*, n.s., xi., p. 202.—Moulmein. Imported by Messrs. Veitch, with whom it flowered in 1879. Flowers white.
 137. D. (EUPHORBIOIDUM) LEUCUM, Rehb. f., *Gard. Chron.*, 1865, p. 67; *Acacia*, ii., t. 145.—Borneo. Introduced by Mr. Hugh Low. Allied to *D. pictum*, but the flowers wholly lilac.
 138. D. LINANUM, Teysm. et Binnend, *Nat. Tijdschr. Nederl. Ind.*, xxv. (1865), reprint p. 4, non Rehb. f. —Java. Buitenzorg Botanic Garden, 1866. Inconspicuous.
 139. D. LINAWANUM, Rehb. f., *Walp. Ann.*, vi., p. 284; *D. noniflorum*, Lindl., non Swartz, *Bot. Beech.*, t. 134; *Bot. Mag.*, t. 4534; Paxt., *Mag. Bot.*, iii., p. 77, with a coloured plate.—A native of China and Japan. Introduced from the former country by the Horticultural Society of London. Flowered by W. Cattle at Barnet in 1829. A very handsome species, with large rose-purple flowers; the labellum tipped with crimson. Hort. Kew.
 - D. LINDLEYI, Steud. = *D. aggregatum*.
 140. D. LINEARIFOLIUM, Teysm. et Binnend, *Nat. Tijdschr. Nederl. Ind.*, xxv., p. 348; Miquel, *Choix de Pl. Jard. Buitenzorg*, t. 23; *D. lineatum*, Teysm. et Binnend, *l. c.*, t. 107, *Bogor*, p. 43.—Sumatra, Java. Buitenzorg Botanic Garden, 1862. An inconspicuous species.

41. D. LINGIFORME, Swartz; Denth., *Fl. Austral.*, vi., p. 284; *Bot. Mag.*, t. 5240; Lindl., *Gen.* and *Sp. Orch.*, p. 85; Rehb. l., *Beetr.*, p. 51.—North-east Australia. Introduced by Mr. Hill, of the Brisbane Botanic Garden, about 1860. A trailing species with small, oval, very thick leaves, and erect slender racemes of small white flowers. An elegant plant. Hort. Kew.
42. D. (EUCHROMIUM) LUTEIFLORUM, Lindl., *Gard. Chron.*, 1856 (May), p. 372; 1867, p. 264; *Bot. Mag.*, t. 6030; Warner, *Sci. Orch.*, vol. 2, t. 3; *D. Hainburyana*, Rehb. l., *Amphiblastia*, vi., Oct. 1856, p. 320.—Assam, Tenasserim, &c., India. First introduced, apparently, by Mr. E. S. Williams, and flowered by Mr. Hainbury. A handsome species, in the way of D. noble, but with longer slender stems, bracts and petals deep purple, lip with a yellowish white zone, extending nearly to the margin. Hort. Kew.
- Var. FREEMANI, Rehb. l., *Gard. Chron.*, n.s., viii., p. 744.—Assam, Freeman. Zone of labellum yellow. Hort. Kew.
- Var. ROSEI, Rehb. l., *Gard. Chron.*, n.s., viii., p. 781.—Larger and finer than the type.
- Var. CANDIDUM, Rehb. l., *Gard. Chron.*, n.s., xiii., p. 586.—A lovely variety, with white flowers.
43. D. LOBATUM, Miq., *Fl. Nederl. Ind.*, iii., p. 631; *Apocyn. Botanicum*, Blume, *Streeke*, *Nederl. Ind.*, p. 237; Lindl., *Gen.* and *Sp. Orch.*, p. 71.—Java. *Batuzorg Botanic Garden*, 1860. Inconspicuous.
44. D. LOBBI, Teijsm et Binndel, *Nederl. Kruidk. Arch.*, iii., p. 360, non Lindl.—Singapore. *Batuzorg Botanic Gardens*, from Mr. Lobbi, in 1852.
45. D. (PELHONUM) LONGICORNIS, Lindl., *Gen. and Sp. Orch.*, p. 80; *Bot. Reg.*, t. 1315.—Sihlet and Nepal, India. Introduced by Dr. Willich in 1828, and flowered in the garden of the Horticultural Society in 1829. A very distinct species, having slender, hairy, or bristly leafy stems, and lateral or terminal white flowers remarkable for their very long spur.
46. D. LONGIFOLLE, Lindl., *Bot. Reg.*, 1840, Misc., p. 172.—Singapore. Introduced by Mr. Cuming for Messrs. Ludlidge. Allied to D. amphim. Flowers pale straw-coloured, tipped with fine purple.
47. D. LOWI, Lindl., *Gard. Chron.*, 1861, p. 1046; *Bot. Mag.*, t. 5393; *Flora de Serravallo*, t. 2, 202, removed from *Bot. Mag.* (Borneo, at an elevation of 5000 feet). Introduced by Mr. Hugh Low. A handsome species of the same group as D. longicornis having flowers of a beautiful rich yellow, the labellum traversed by longitudinal lines of long hairs springing from crimson bases. Hort. Kew.
48. D. LUGENS, Rehb. l., *Bot. Zeit.*, 1863, p. 123; *Venus*, n., p. 132, t. 146.—Borneo. Discovered and introduced by Mr. Hugh Low for Messrs. Low & Co., of Ceylon, in whose nursery it first flowered in 1862. Allied to D. pictum. Flowers whitish, with some purple-brown; labellum with an orange disc.
49. D. LUTEOLUM, Bateman, *Gard. Chron.*, 1864, p. 264; *Bot. Mag.*, t. 5441.—Moulmein. Introduced by the Rev. C. S. Parish for Messrs. Low, of Ceylon. A beautiful flower-flowering Dendrobium of the D. aureum type, of which, indeed, it may be no more than an unusually luxuriant strain with primrose flowers, and a little orange and crimson on the lip. Hort. Kew.
50. D. LUTRACULUM, (L.) W. & A., Hooker, *Bot. Mag.*, t. 4899; *Gard. Chron.*, 1856, p. 102.—Ceylon, in the forests about Ratnapura and towards the hills. Stems long and slender, bearing leaves and flowers at the same time; the latter of the most gorgeous kind, the prevailing colour being a purplish rose. Hort. Kew.
51. D. MAYRATI, Lindl., *Gen. and Sp. Orch.*, n. 27; *Tournef. Linn. Soc.*, iii., p. 6.—Ceylon and Western Peninsula of India. Flowered at Kew in 1866.
- D. MAYRATHIUM, Hook.—D. superbum.
- D. MACROPHYLLUM, Lindl.—D. superbum.
52. D. MACRORHIZUM (*List of Orchids Cultivated in the Glasgow Botanic Garden*, 1881).—Australia? Apparently an unpublished species.
53. D. MENSCHINGII, (L.) W. & A., Parish for Messrs. Low, *Fl. de l'Archipel*, Atlas, t. 6, 133; *Heb. Ann.*, vi., p. 304; *Bot. Mag.*, t. 5540 (var. *Nottinghamii*); *De Vries Ill.*, t. 5; D. *Vestibulum*, Lindl., *Bot. Reg.*, 1847, sub t. 25. Java. Introduced by Mr. Thos. Lobb for Messrs. Venter. A tall-growing species, with broad leaves and long terminal spikes of greenish-yellow flowers, hairy outside; lip 3-lobed, stippled and spotted with purple. Hort. Kew.
- Var. PAVANUM, Hugh Low, *Hamb. Gartenz.*, xiv., p. 211.—Borneo. Introduced by Mr. Hugh Low, and cultivated by Messrs. Low, of Ceylon. A very fine variety.
- D. MACROSTACHYUM, Lindl., *Gen. and Sp. Orch.*, p. 78; *Bot. Reg.*, t. 1365; Wight, *Re. Pl. Ind.*, v., t. 1547, p. 85. Borneo. Described by Macrae, and cultivated from a fragment found in his dried collection. Mr. Bateman flowered it in 1830. Stems long and slender, bearing the flowers usually in clusters of three. Flowers pale yellow. Hort. Kew.
- D. MILENA, Hort. Belg.—D. MACROPHYLLUM, var., ex Planche, Hort. Donat.
55. D. MARGINATUM, Bateman, *Bot. Mag.*, t. 5154.—Moulmein. Introduced by the Rev. C. S. P. Parish for Messrs. Hugh Low & Co. Very closely allied to D. aureum, and perhaps better regarded

as a variety of this species. It has a showy orange and crimson labellum, bordered with white. I think I have somewhere seen a statement that this is the same as D. xanthophloeum.

W. B. HENSLY. (To be continued.)

NEW DAFFODILS.

NARCISSUS MASTERIANUS n. sp.—In May last I sent to you (*vide* p. 603 *Gard. Chron.*, May 7, 1881) what I there call a Polyanthus Daffodil (*Narcissus tridymus*), the first of its race, and differing from all other Daffodils in having more than one flower on a stalk. I now venture to send you a sketch of a very pretty Narcissus—I am almost afraid to call it a Daffodil, and yet it comes pretty near to the large trunked section of the genus. N. Macleani is perhaps its nearest relative, but we have here three flowers on a scape, and the colours are quite different. A glance at the illustration (fig. 76) will give a better idea of this novelty than any amount of mere description. It is a seedling raised by the Rev. J. G. Nelson, of Aldborough Rectory, near Norwich, and has been by him (or my friend Mr. Barr, perhaps) called N. Masterianus x. The perianth segments are creamy, or French-white, and the cup is of a soft pale primrose tint—together a very chaste and pleasing flower, quite

FIG. 76.—NARCISSUS MASTERIANUS.

unlike anything else I know in the genus. The scape is about 9 inches in height, and much fluted; the leaves, I presume, are flat. The perfume is faint and Daffodil-like—not the rich full fragrance of the Narcissus of the N. Tazetta group. Of its parentage, leaves, and habit of growth or constitutional vigour, Mr. Nelson may some day, at his leisure, I trust, tell us something, for of all men the actual raiser knows most worth the telling of these matters.

NARCISSUS GERTRUDE JERYLL.—Also from Mr. Nelson comes a most remarkable Daffodil of the N. moschatii bicolor group, a fine bold and distinct flower, of a clear sulphur yellow, stained or suffused with gamboge-yellow. The trunk, or corona, is 2 inches in length, also clear sulphur, with a deeper coloured rim. It has a beeswax-like odour, which suggests its being related to N. moschatii, but the perianth and trunk are of a finer texture, indeed in form and size the flower is that of N. bicolor Horsfieldii, but, as we have already shown, the colour is very different. It is named Gertrude Jekyll, in compliance to a lover of hardly flowers.

NARCISSUS OVALARIAS VAR. GRAND TRUNK.—Yet another Daffodil quite strange to me comes from Mr. T. Smith, of Newry. It is doubtless the N. ovalariis maximus, and quite different from N.

maximus, or College Garden Daffodil, from which it differs in having a shorter and broader trunk, the perianth segments being also broader and more imbricate than is the case in the flowers of the last-named kind. Mr. Smith's name of Grand Trunk Daffodil may well serve for this, which is doubtless a grand form of the smaller Tenly Daffodil, N. ovalariis. It is a grand flower. F. W. Barbridge.

INDIA-RUBBER.

ACCORDING to Messrs. Hecht, Lewis & Kahn's report for 1880, the total import of Para rubber (Hevea) into England during the year was 3768 tons, of which 3601 tons during the year went into consumption or was exported. Liverpool received 35 tons of Ceara scrap rubber (Manihot), 100 tons of Guayaquil and Carthagena (Castillo) most of which went its way to the United States, and 1300 tons of (West) African (Landolphia), of which "all kinds were readily taken by consumers and exporters," notwithstanding an increase in the imports of the year of 400 tons. London imported 370 tons from Assam (Ficus), 530 tons from Borneo (Willughbeia), and 900 from Mozambique (Landolphia).

The constant demand for caoutchouc for manufacturing purposes, and the efforts made by the Government of India to foster the cultivation of rubber plants, especially the South American kinds, has turned the attention of planters in our tropical colonies to the subject. A rather active correspondence has sprung up with Kew for information as to the little investigated native sources of commercial caoutchouc other than the South American, which has been so prominent a topic in preceding reports. A considerable body of information, especially regarding rubber-yielding plants of the natural order Apocynaceae, has gradually accumulated, as the result of inquiry, and this has been carefully examined by the Assistant-Director, who proposes to communicate the more strictly scientific results, with descriptions of the new species, to the Linnean Society. The following abstract of the economic aspects of the subject will, I trust, be found useful by our colonial and Indian correspondents. It is arranged under geographical heads.

AFRICA.—All the present commercial sources of African caoutchouc belong to the genus Landolphia. This is a group of woody climbers, all of which probably yield caoutchouc regular to Tropical Africa and the adjacent islands. African caoutchouc comes into commerce both from the west and the east coasts, and only one of the rubber-vines is common to both. The following are the rubber-yielding species at present known:—

West Coast.—1. L. owariensis is apparently the species possessing greatest latitudinal range. The genus Landolphia was founded upon specimens of it collected in Oware by Falisot de Beauvois, and it extends from Sierra Leone, where it was collected by Lin. to Angola, from which Kew possesses specimens from Welwitsch and Monteiro. It was collected on the Niger by Barter, and near the mouth of the Congo by R. C. Phillips (who states that it bears the native name of Mvoochi). A form, not specifically distinguishable, was found by Schweinfurth in North Central Africa. He remarks (*Heart of Africa*, i, 192) that "it is well known in the Guinea trade for its production of caoutchouc. From the fruit the source of which exceeds that of the cotton," the natives of Djur-lund manufacture "a beverage refreshing as lemonade."

The plant figured by Collins (*Report on Caoutchouc*, pl. 4) as L. owariensis, differs, especially in its minute flowers, from the species as defined by Falisot de Beauvois, and is possibly founded upon materials belonging to some other.

2. L. Mannii, sp. n.—A very distinct species, collected by Gustav Mann at Corisco Bay (lat. 1° N.), and not at present known from any other locality. Mann describes it as a climber 20 feet high, and yielding caoutchouc.

3. L. florida.—This beautiful species, originally described in the *Niger Flora* by Bentham, appears to be distributed over the whole of Central Tropical Africa. Its heads of large sweet-scented Jasmine-like flowers would render it a desirable introduction, from merely a horticultural point of view, in stove-cultivation. On the Niger, according to Barter, its fruit, which is very sour, is eaten by the natives under the name of Aboli. According to Monteiro, who collected specimens in Angola, the indiarubber of South-west Africa is derived from this.

Further information on the subject of Landolphia florida may be found in Thomas Christy's *New Commercial Plants* (No. 1, accompanied by a good figure) as well as below, amongst the East Coast species. *Report of Royal Gardens, Kew*, 1880.

(To be continued.)

HOME CORRESPONDENCE.

Wild Flowers at Matlock.—The remarks on p. 436 about the depredations to which wild flowers are now subjected met my eye on Saturday last, just as I had returned from a visit to Matlock, a place I have known well all my life. It used to be one of the most favoured homes in England for rare and pretty wild flowers and Ferns, but they are fast disappearing, and the most conspicuous of them are already extinct. Fifty years ago I was told by an old lady, my grandmother's contemporary, how, when a girl, she had seen *Cypripedium Calceolus* growing wild on the Heights of Abraham, just opposite to the Matlock High-Tor. In my boyhood the Bee and the Fly Orchis were common plants on the steep limestone sides of Masson Hill. These have been for long becoming rarer year by year, and are now probably extinct. I knew of a colony of Fly Orchis in a secluded spot, consisting of about a dozen plants, and visited it three weeks ago, when they were all safe and just above-ground. Last year I went past the spot and found every plant gone, and the marauders had not even had enough regard for appearance to fill up the trowel holes, which were less than a week old. I mentioned lately how entirely *Helleborus foetidus* has disappeared. Twenty years ago I saw many plants of that finest of the Dandelion tribe, *Hypochaeris maculata*, in a field close to Matlock Bath Church, but this too has quite disappeared. Of Ferns, *Polypodium calcareum*, formerly common, is extinct. *Cystopteris fragilis*, which used to cover the walls by the side of the turnpike road, has to be hunted for in remote corners, and even the common Hart's-tongue is rare in places of public resort. But there is much near Matlock still to interest the botanist; some plants, so conspicuous that it is a wonder how they have hitherto escaped, had better not be mentioned: but two or three, which are defended by their local abundance, or their obscurity, may be noticed. The mine hillocks are crowded in May with large plants of *Arenaria verna* covered with snowy white flowers. The sides of the limestone hills, where the grass is short, contain abundance of *Thlaspi alpestre* now in flower, I suppose of the variety called by Sowerby virens, for which Matlock is given as the only habitat. *Draba muralis* occurs more sparingly, and is easily overlooked, and *Cardamine impatiens* grows on the walls by the roadside in the very town of Matlock Bath. The Lily of the Valley grows in abundance about 3 miles from Matlock, but is so persecuted by marauders that the owner of the wood where it grows has established a regular society of watchmen to preserve it. *C. Woley Dod, Edge Hall, Malpas.*

Rhododendron Dalhousie.—Will you permit me to mention in your journal, as I did to the Scientific Committee, that I owed the truss of R. Dalhousie to Messrs. Downie & Laird, of Edinburgh, whose magnificent plant I saw last year in their nursery. The greenish-yellow form, as stated by Sir J. Hooker, is the most common in cultivation, and also its native home. The white form, curiously enough, is almost exactly presented by a hybrid raised by Mr. Anderson-Henry between the true species and R. formosum. *J. H. Mangley, Valewood, Haslemere.*

The Fruit Crop.—Notwithstanding the adverse change that took place in the weather when the country was visited with a fall of snow and pelting cold rain, succeeded by sharp frosts and cutting winds, I am glad to be able to state that the fruit crop round about here has taken but little harm, and that the "set" of Peaches, Nectarines, and Apricots is something prodigious. If all goes on well from now we shall have a pleasure we have not had for years past, that of thinning and making choice of fruit, and having it regularly distributed over the tree; but we are not yet out of the wood, for while I write the wind is blowing from the north-east and has the sting in it usually has when it comes from that quarter. Pears are sure to be thin, as the trees have but little bloom showing, the paucity of this arising from the heavy load most of them had to bear last season. Cherries are very full and will soon be quite a sight, as the blossoms are now fast expanding, and Plums are equally promising and look strong and well. Apples are not so regular, some sorts being crowded with bloom-buds, while others are thin or have none at all. The mild winter has just suited Figs, the wood of which is studded with embryo fruit, and if half of it stands there will be a fine crop. Gooseberries have got a little touched by the frost, but the bushes were so full they could well bear the loss of a few. Currants were not sufficiently forward to be injured, and

from present appearances the crop of these will be good. Strawberries could not possibly look better, the summer and autumn of last year being particularly favourable for the development of fine crowns, and the plants are therefore very strong and robust, with plenty of old foliage to protect the young when it comes. *J. S.*

Wholesale Destruction of Wild Flowers.—I am very glad to see this latter mooted in the *Gardener's Chronicle*, and I do most sincerely trust that the ruthless traffic now carried on in some country districts may be put a stop to. I went yesterday to a copse about half a mile distant from this place, which is in spring full of Primroses. There was not a single flower to be seen. I at first thought that the village children had been gathering them, although if they had blossomed this spring as plentifully as they had been wont to do, it would have taken several hamper to hold their bloom. A closer investigation showed me that roots and all were gone, and then I remembered the Fern-gatherer of the neighbourhood—a man who has nearly destroyed every vestige of Fern and moss for miles around, in order to start large baskets full to London by train. He gets well paid, he says, at Covent Garden, and, alas! spends his gains in drink, leaving his really hard-working wife to toil for herself and numerous family, likewise keep a house for him when his flower and Fern money has been spent in the public beer shop. The country, God-made country, would no longer be a country without those beautiful "wildlings of Nature." As Ann Pratt says—

"I love the field flowers too,
Because they are a blessing given
Even to the poorest little one
That wanders 'neath the vault of Heaven.
The garden flowers are raised for few,
And to that few belong alone,
But would the flowers of the vale or stream,
Each one may claim them for his own."

If its own to enjoy, but not cruelly uproot for sale, leaving the hedges and woodlands bare of floral beauty. *Allen E. Watney.*

Evergreen Berberis.—Among the Berberis that stand out most conspicuously for beauty and general usefulness is B. Darwinii, which is just now laden with its racemes of orange-coloured blossoms that quite light up shrubberies or borders in which plants are growing. Rich and glowing as the flowers are the beauty of B. Darwinii does not end with them, as by-and-bye the branches will be borne down by the weight of the rich blue-black berries, that are almost as great an ornament as the bloom, and all the year through it is one of the most pleasing-looking shrubs on account of its graceful habit and foliage. Next, or perhaps equal to it in point of merit, is B. stenophylla, which is more prostrate and spreading in its manner of growth, and is therefore better adapted for banks or mounds and rockwork, or other similarly elevated positions; so placed, plants of this kind arch and droop over in the most pleasing manner possible, and look quite at home. B. Aquifolia is too well known to need any notice, as it is one of the shrubs that may be met with almost everywhere, and one that can hardly be misplaced, as it will succeed under the drip of trees, in woods, in dense shade, and in dry black situations where nothing else will grow. B. Darwinii needs shelter, as in exposed positions much open to the wind and cold it gets much cut about if the winter or spring happens to be very sharp or cold, and the same with B. stenophylla, which is a hybrid raised from the above named. The transplanting of Berberis is a ticklish operation, and unless caught just at the right time many losses occur. The best season, or at least the one I have always been most successful in, is early in April, just as they are beginning to grow, as then root action is simultaneous, and they soon send out hosts of young feeders, and get fresh hold of the ground; planted earlier, the winds dry them through, and the bark shrivels, and when this occurs, if they live, they seldom do well. In planting Berberis the most important point to attend to, next to lifting them carefully, is to well wash part of the soil in about the roots before finally filling up the holes in which they are placed, and if, after that, they are mulched, scarcely one in a hundred will fail, as the mulching prevents any drying or cracking of the earth around, and greatly encourages the formation of fibrils, which, under its fostering aid, soon extend and get firm hold of the ground. *J. Sheppard.*

The Two Tacsonias, Van Volxemi and exoniensis.—Permit me to endorse all that "J. H." so well says of the extreme beauty and chaste and graceful appearance of these two superb climbers. I have not had the pleasure of seeing the fine example at Longford Castle that your correspondent describes, but have seen one or both in fine condition at many places, and have had them mixed on our roof here for some years. They are best mixed, for several reasons, and the roof or arch,

not the wall, is the best place for them. The mixture has the merit of being earlier in flower, as exoniensis precedes by a month or more Van Volxemi; it also flowers later—in fact, with us *Tacsonia exoniensis* is hardly ever out of flower. Again, the colours, though closely related—crimson and bright pink—harmonise beautifully, and the two together form a richer display than either alone, though any one of these forms a glorious drapery by itself. The leaf-stalks are also of different lengths—that of Van Volxemi being nearly double the length, and much more slender than exoniensis. The result of this is extremely beautiful; the longer and more brilliant flowers seem suspended on invisible cords, and drop away, seeming almost to fall down or be suspended on gossamer-like threads in mid-air, close to the spectator; while the higher roof-sphere, to coin an expressive phrase, is draped with the lighter, larger, and more strongly stemmed blooms of *Tacsonia exoniensis*. The foliage too differs widely, as in the flowers, enhancing the effect of the verdure. The tendrils again—an important feature of the beauty of these plants—also differ as widely as the flowers. And yet somehow all these differences seem to link the two plants into a more homogeneous and lavish wealth of beauty. Much of this beauty is necessarily lost when the Tacsonias are grown on walls. It is only as they weep gracefully over arches, eliche and drape with drooping pendants girder or rather, that the full face and charm of character of these plants can be fully seen. Exquisitely beautiful when at rest, they are still more so, as "J. H." points out, when swayed softly to and fro by the wind, or violently tossed aside by a rush of air from open doors or ventilators. The effect has been tried here of converting this matchless unity into a trinity of colour as well as form. Two white plants succeeded in doing this more or less perfectly; both are old-fashioned and little grown, but none the less valuable on that account. They are the Mandevilla, saulevallis, and the Solanum jasminoides. Both are graceful if grown and trained in the free and easy style suited to the Tacsonias, and the first is one of the sweetest plants in cultivation. Unless grown in pots, tubs, or portions of borders, barricaded against the greedy gross roots of the Tacsonias, neither of these plants are able to compete against them for any length of time. Where they can be made to thrive and add their white sheen to the brilliancy of those of the Tacsonias, it matters little what or whether anything else be in the plants can be rivets all eyes, and holds them so firmly in its attractive grasp with its three-stranded cord of colour, form, grace, that hardly a glance can be spared for aught below or around it. The individual flowers are penshable, and of little value for cutting; still branchlets in full bloom, leafage, and tendrils, may be carried through a dinner or evening party, and give a unique character to large baskets, vases, &c. Single flowers placed in damp moss mass well with Eucharis, Panchatanus, or Lilies. As to the plants and forms these draping the roof with a wild profusion of growth and bloom that the full beauty of these glorious Tacsonias is fully revealed. *D. T. F.*

The Early Spring.—The spring has been remarkable for the strange way in which some flowers have put in an appearance. The first that appeared was *Muscari botryoides azurea*, which has been in flower since the first week in January, in fact there were flowers gathered before Christmas. *Saxifraga Borsieriana* lost its place this year, having been forestalled by *S. Kocheliana* by a week or ten days. The yellow vernal Crocus, contrary to rule, was in full flower before the Snowdrop in my garden, and I have heard several persons make the remark as having occurred with them. The double dark crimson Primrose was one of the first to show in that family, having only the single white before it. *Primula nivalis* or *rosea*, *P. marginata*, *P. purpurea*, are past and gone—*P. nivea*, *P. denticulata*, and the Cashmere variety being now in full beauty. *Erythronium giganteum* is very fine, and the yellow americana fuller of flower than usual. *Chionodoxa Lucida* (established bulbs) has been particularly fine, as well as its near relative *Fuschkina*, a plant too seldom met with. *Corbularia Clusii* has been larger and finer than usual; and many other spring flowers fully six weeks earlier than last spring. At the same time I am under an impression that, on taking stock, it will be found that more alpine and hardy herbaceous plants have died than in the springs of 1880 and 1881. *Alpha, Cheshire.*

Bees in Peach-houses.—I quite believe with Mr. Muir that these are good for the trees and ensure a good set; but what of the effects on the bees? The other time I have tried it I have been unfortunate. The first time a gamekeeper promised me a hive, going into the house shortly after I found an empty skep. That was many years ago, and the good man thought the bees were wanted as a charm, and that a skep would do as well as the hive; the house proved as potential for good as the busy tenants. The next time the bees rushed out, set to work with vigour, but as soon as the clouds obscured the sun and evening drew near, the bees, instead of returning to the

hive, proceeded to batter and bruise themselves against the glass, where many of them seemed to die in the morning. The next day few of them seemed inclined to gather honey from the myriads of open Peach blooms and so set the fruit. Home sickness seemed to come over the bees, and they did not recognise their old home in the new quarters, but tried hard to get back to the old place of last year, a mile distant as the bee or crowd flies. Those that could escape did so and perished under the old house, those that remained killed themselves so fast or bruised themselves so much, and became so restless and enraged, that on the second night any that had returned to or remained in the skep were carried home. That hive did little good the next year, which leads me to ask Mr. Muir how his bees fared after his work of setting was over, and what of their present condition, and how many were left dead in his Peach-house. D. T. F.

Primula rosea.—This is certainly one of the prettiest, if not the prettiest, of all the hardy Primroses. It is now a blaze of beauty, and its bright rosy blossoms make it the most conspicuous thing on the rockery. It is very dwarf in habit, and very easy of culture. The year before last we had but one plant; last year I divided it up into twelve or thirteen small crowns, and all grew, and all but two were flowering this spring. The crowns are from 4 to 5 inches across, with five or six stalks of bloom, bearing in some instances as many as thirteen individual blooms; it is about 4 to 5 inches in height. For the front row of the herbaceous border, or allowed to grow into masses on the rockery, it scarcely has a rival, and those who do not know it should get a plant or two. W. L., *Bromsgrove*.

Rose Gloire de Dijon.—We cut our first well blown Rose Gloire de Dijon on March 7; since then we have cut two more perfect flowers from the same tree in the open border, and it is now covered with well-formed, clean buds, ready to open when the present cold east wind ceases. *Gertrude Hope, Belmont, Murrayfield, Mid-Lothian, April 3.*

Miles' Egonette.—I think it is hardly possible to over estimate the value of this splendid variety. We have now some plants in full bloom, some in 6-inch and others in larger pots up to 9-inch. The seed was sown last August, and the pots were placed in a cold pit, the frost just kept from them until about the middle of December, when they were removed to the Pelargonium-house, and soon began to grow away very strongly; and now some of the plants in 9-inch pots are nearly 5 feet through, and about 2 feet in height—a mass of bloom, and exceedingly effective in the conservatory. T. Pope.

Fruit Prospects in South Wilts.—Thanks to well ripened wood and well matured buds, consequent on our being favoured last year with more than an average amount of sunshine, fruit prospects in and around this district are extremely promising at the present time, and should the weather continue anything like as favourable in the future as it has been in the past we may confidently look forward to an abundant crop all round. Apricots, Peaches, and Nectarines have presented a most picturesque appearance during their flowering period, so abundant was the blossom; those growing on south aspects have set wonderfully well, and indeed their numbers—untoward events and circumstances excepted—will have to be considerably reduced. Of those growing on east and west aspects it is as yet too early to speak with anything like confidence; the flowers, however, are quite firm to the touch, and that of course is an encouraging sign. Plum and early varieties of Pears, which are now in full blossom, are all that one can desire, the flowers being strong and plentiful. Apples and Cherries are also showing well, and promise to be, as last year, one mass of bloom; good Apple years, however, in our immediate locality are so few and far between, owing to our situation being low and damp, that we are compelled to look forward to the next few weeks with a certain amount of scepticism, and mixed with hopes and fears and feelings of interest and anxiety, as to whether we are to have our usual number of late frosts, which frequently prove so destructive. If it were possible to apply the *clitao* to Jack Frost we should most decidedly do so this spring, as we have not had a good crop of Apples since 1875, and we have begun to think that by this time we are fairly entitled to one.

Small fruits, with favourable weather, are likely to be plentiful judging by present appearances; but, of course, a sharp frost or two within the next few days would very materially damage the crop of Gooseberries and Red Currants, owing to their now being in full flower. Strawberries, Raspberries, and Black Currants, look promising and well, the same remark is applicable to Figs, Medlars, Quinces, and Filberts. We are not yet out of the wood, and will not be, so to speak, for six or eight weeks; it would therefore be alike unwise and unsafe to prophesy this early. The outlook, at all events for the time being, is cheerful and encouraging. J. Horsfield, *Heywood, April 3.*

Rock Plants in Flower at Hooles House, Chester.—Admirers of alpine plants would do well to visit Hooles House, the residence of Mrs. Hamilton. The place is situated about 1 mile from Chester, and is within easy access of either the general or Victoria stations. Having occasion to visit this place a day or two ago I was amply repaid for my journey. The rockery, which is built chiefly of white coral stone, is a sight difficult to describe. *Aubrietia purpurea* is now a perfect sheet of bloom, here and there dotted amongst it being specimens of *Arabis alba* and *Alyssum saxatile*, and the common *Primrose*, the yellow and white contrasting nicely with the *Aubrietia*. On the lower part of the rock I noticed nice patches of *Anemone pennina* and its white congener *alba*. Various *Saxifrages*, *Burscheriana*, *Wallacet*, *crassifolia*, *Rocheletiana*, muscoides, and all muscoides, *Androsace*, *Primula*, too, seem to grow luxuriantly here; fine examples of *cashmiriana*, *marginata*, *farinosa*, *claviflora*, and *platyptala plena*, the latter having five-four expanded flowers on a small plant. I may also mention *Iberis gibraltarica*, which has done well; this winter seems to have suited it. Also a nice specimen of *Gentiana verna* with its pretty blue flowers seems quite at home in a shady nook, and *acaulis* seems to be well established and producing a considerable quantity in full flower. I could add that everything looked neat and clean, which reflects great credit on the gardener, Mr. Thompson, who takes a deep interest in herbaceous and alpine plants. *James McNab, Chester.*

Mildness of the Season in Edinburgh.—It may interest you to have some other proofs of the remarkable mildness of the past winter from this quarter. On March 20 a Horse Chestnut tree was in leaf here, and since that day and before the end of March several others have come into leaf, as also several Sycamore, Elm, and even Lime and Birch trees. A standard Pear tree about 18 feet high is covered with blossom, the greater part only in bud, and a considerable quantity in full flower. The Camella of which I wrote you in my last, and which is about 6 feet and not 4 feet high, has been going on flowering ever since, and has now no fewer than twenty-four open flowers upon it. Might I suggest that an annual tabulated statement, collected by reliable persons at different selected parts of the kingdom in answer to a list of the same questions annually furnished to them by yourself bearing upon the times of first flowering and first coming into leaf, &c., would not only be very interesting, but in course of years would be valuable? As far as my own observation has hitherto gone the Sycamore is usually the earliest of the trees above-mentioned in leaf here, but this year the Horse Chestnuts have been the earliest. Can you inform me which is usually the earliest in the South? The effect of different kinds of winter weather upon the different trees seems to offer an interesting field for observation. The priority in some years of the Oak and in others of the Ash is a well known instance. T. Ivory. [It is essential to observe each year some individual tree, as there is a great variation in different trees of the same species. Ed.]

African Tuberoses.—Early last autumn a quantity of these bulbs were imported from the African continent, and being very much larger than those imported from America (which by the way generally arrive in this country about Christmas) they were readily picked up by enterprising growers, who well know that the earlier these blooms are sent to market the more money they realise. An ample return was naturally expected for the capital invested, and the trouble bestowed upon them. Accordingly the bulbs were planted and tended in the usual manner, and in due time a strong and vigorous spike was thrown up, which gave promise of abundant bloom, but, alas! just as the flower-buds were on the eve of expanding they withered and decayed, and where success was expected failure occurred. Some of the growers may be deterred from relating their experience in this case lest they might be accused of bad cultivation or neglect; but after having visited the grounds of one who has for years been a successful grower of Tuberoses, and found that about 2000 African bulbs behaved themselves in the manner indicated, and that the sad tale that has to be told of them is that none produced a solitary bloom, and having heard similar reports from other friends, I am convinced that the failure of the African Tuberoses is not due to bad cultivation; we must look elsewhere for the cause. The opinion of many is that only large bulbs produce the best blooms, but the African Tuberoses, with its fine large bulb, militates against this idea, while careful and enquiring cultivators have observed that large bulbs throw up a strong spike and make very few roots, so that when all the material stored in the bulb has been exhausted in building up the spike, and just as the flowers are to open, the plant has no communication with the soil by which to obtain more nourishment, and consequently perishes without having fulfilled its function. J. McK.

Florists' Flowers.

AURICULAS IN THE NORTH.—As far as Cheshire is concerned, we are fully six weeks earlier than last year. In looking over a collection (March 24) of from 1200 to 1600 blooming plants, I was surprised to find so many fully expanded, and am of opinion that we are quite as early as the South, having had better weather I believe. It is a general complaint that the plants have been growing all the winter, and have never been less trouble to keep free from fly. Complaints are made in some places that more plants than usual showed bloom in autumn, which will tell against a good spring bloom. I do not know that I ever saw a stronger or finer bloom of *Acme* (Read) than is now open; Colonel Champneys (Turner) is past its best; Kinglander (Kenyon's), Mrs. Butcher (Clegg's), Duke of Wellington (Dickson's), Meteor Flag (Lightbody), Pizaro, are now at their best; Blackbird (Spalding's), Lord of Lorne (Campbell's), Glory (Taylor's), Freedom (Booth), and Prince of Greens (Trail), are very strong, and showing well. Polyanthus are now at their best; Alexander (Pearson's) has been in flower since Christmas, and is very fine; Lancashire Hero, George IV. (Buck's), Lord Lincoln, and Exile, are very fine, and if the present warm weather continues I fear there will be few flowers for the Northern show on May 2. *Exile*.

THE AMARYLLIS.—There is no doubt a great future in store for this showy exotic; indeed, the demand already for bulbs of the best varieties is much in excess of the supply, and as they are very expensive it is important that they have the treatment best suited to keep them in good health. The bulbs having been rested in the winter, they are usually started very early in the year—January and February. They are grown on in heat; probably the pots in which they are growing have also been plunged in bottom-heat; and as soon as the flowers open, which is in March and April, probably they are removed to the greenhouse. There is no doubt but that this gives the plants a considerable check; and what is worse, in many cases they are not well attended to after flowering is over. If it is necessary to remove the plants to the greenhouse while they are in flower, if possible keep the house a few degrees warmer, also closer, while they are there; and as soon as flowering is over take them back to the warm house immediately, as they have nothing like half completed their growth when flowering is over; indeed, they should be kept in a growing condition until the end of August, when water must be gradually withheld. When the plants are in growth they must not be exposed to too much sunshine, and the house must not be too freely aired. If the pots are plunged the bulbs may easily be injured by getting too much water; once or twice a week may be sufficient, while those arranged on stages may require it every day, or at least every alternate day. I have frequently seen good healthy bulbs injured by having too much water given to them before a sufficient number of roots had been formed to take it up; when the plants have formed leaves, and are growing freely, there is not so much danger. J. Douglas.

THE CARNATION AND PICOETE.—From observations made in our own garden, and by what I can hear from other districts, these are earlier in proportion than some other flowers. Mr. Gorton writes from Manchester to say that his Auriculas are not earlier than usual, but that the Carnations are very much earlier, so much so that he finished potting on March 10 this season, while they did not finish last year until April 10. Our own were finished in February, and they are already spindling for bloom. I fancy the repotting of Carnations and Picoetes is often delayed until it is too late, and the flower-stems run up if warm weather sets in very rapidly before the roots have taken good hold of the new compost. These, therefore, who have not yet repotted their plants should see to it without any delay. We look over our potting material at least three times for wire-worms, and even after this careful inspection some of

them are missed, and much injury is caused to the collection, as if one of these dreary pests gets into a pot it is sure to destroy the plants. Many persons do not report until this time because they are obliged to put their plants out-of-doors as they are potted; and that is the case early potting would not be desirable. We are always able to put our plants under glass lights until they are well rooted into the new soil. The best compost is good loam from the top spit of an old pasture; four parts of this to one of rotten stable-manure, one of leaf-mould, and nearly as much sharp river-sand. It is now a good time to propagate and pot off young stock of tree Carnations. The first batch of cuttings ought to have been put in during the month of January or February, at the latest; the best place for them being a propagating-house where the temperature is not too high—55° at night is quite high enough. As soon as they are rooted the young plants ought to be potted off singly in small pots, still keeping them in this house until they are established, when they may be put out into cold frames. They are subject to the attacks of greenfly, which must not be allowed to remain on them. They must be potted on and carefully treated, else they will not make strong flowering plants by the end of the year. J. D.

FORCING PINKS.—The first of these are now coming into flower, and those in cool-houses or frames are making strong healthy growth. As soon as small side-growths can be obtained they should be taken off and be put in as cuttings; they will strike out roots as freely as *Verbenas* in a hot-bed. It is very desirable to get off the cuttings as early as possible after April 1. Unless they are put in as early as this they will not form strong clumps for forcing. We get a score or more of good flowers from each plant propagated in April. They require but little attention, as they are merely planted out on a vacant piece of ground in the kitchen garden as soon as they are well rooted. J. Douglas.

Notices of Books.

Paxton's Flower Garden. By Professor Lindley and Sir Joseph Paxton. Revised by Thomas Baines. Vol. I. (Cassell & Co.)

The original edition of this work appeared some thirty years ago, and was the joint production of an eminent gardener and an eminent botanist. It was, therefore, no mere compilation, but a work of authority and original research, and as such it is often quoted and its figures frequently referred to. There is no need, therefore, to advert at length to the value of a book which those conversant with horticultural literature have long ago appraised. That Mr. Baines' personal contributions to the new edition are of great value no one who knows him will doubt, but of his editorial supervision of other men's work we cannot speak so highly. Indeed we can but feel that an injustice has been done by the publishers to the memory of Paxton and Lindley in issuing this edition under the old title. Many of the plants of which coloured representations are given are new introductions since the time of Paxton and Lindley—a fact mentioned indeed in the preface, but which the ordinary reader turning to any particular plant will not always be able to recognize. Surely such introduction of new material should have been indicated with the Editor's initials, or some other means of making apparent the distinction between the original text and his additions have been adopted. The numbering of the plates is necessarily altered in the new edition, so that in quoting them it will be needful in future to specify the second edition. The execution of these plates, especially as regards the colouring, is often anything but satisfactory.

In turning to the Gleanings and Original Memoranda—perhaps the most valuable part of the former edition—we find no indication of what is new and what is old. For instance, on p. 6, *Dracena Goldiana* is sandwiched in between *Metrosideros Tomentosa* (why is a capital T used in this and other cases where its use is unusual?) and *Berberis japonica*. A quotation from this journal does, indeed, afford to those who are already familiar with the date of the original publication of the *Flower Garden* an indication of the intercalated matter, but to the amateur, or young gardener, with his business to learn, there is nothing to show that *Dracena Goldiana* was unknown to Paxton and Lindley—it might, indeed, be

paradoxically inferred from this book that it was. On the other hand, in cases where editorial revision was needed, it has been withheld—for instance, the plant figured as *Abies jezoensis* in the old edition is still allowed to retain that name, though it was pointed out many years ago by Mr. Andrew Murray not to be that species, but rather a new one, to which Murray gave the name *A. Fortunei*, and which has ever since been known under that name. Of course, owing to the lapse of time and the increase of knowledge, there are many cases of similar nature which an editor would be justified in altering so as to bring the information down to the most recent date. It is abundantly certain that Dr. Lindley, were he still living, would not have failed to make such alterations as the necessities of the case demanded.

The practice of giving English names, which Lindley, among others, advocated, and to a certain extent succeeded in introducing, and which is carried out here, is surely one which must be adopted or rejected as convenience, common sense, and good taste dictate; for instance, is it not easier and less open to misconception to say *Cypripedium venustum* rather than "the handsome lady's-slipper"; *C. javanicum* rather than "the Java lady's-slipper"; *C. barbatum* rather than "the bearded lady's-slipper"; *C. purpuratum* than "the purple-stained lady's-slipper"; *C. Lowii* than "Low's lady's-slipper"; *C. glanduliflorum* than "the glandular lady's-slipper"; *C. insigne* than "the bannered lady's-slipper"; *C. carolinianum* than "the sedgy lady's-slipper"; or *C. caudatum* rather than "the long-tailed lady's-slipper" (p. 59)? The Latin designation is the simpler of the two, and although in the English version the connecting hyphen conveys the proper meaning to the eye it would often be omitted in writing, while in conversation the difficulty of correctly indicating the meaning might possibly lead to embarrassing complications.

While we have deemed it necessary as an act of justice to the memory of our predecessors to allude to the manner in which this new edition has been issued it would be quite as unfair to the present editor to omit reference to those portions of the book which are distinctively his. The opinion of no one is more highly valued on cultural matters than that of Mr. Baines, and his experience, taste, and judgment in the selection of plants, especially worthy of cultivation from a decorative point of view, will give special value to this edition. As a record of what is best among both old and new plants Paxton's *Flower Garden* in its new guise will be as useful as before, and in its cultural details even more so.

Elémens de Botanique Agricole, &c. Par E. Schribaux and J. Manot. Paris: Baillière.

A treatise on the morphology and physiology of flowering plants adapted for use in agricultural schools, and containing, therefore, fuller information as to certain cultural processes, such as grafting, layering, &c., than is usual in books of this character. A supplemental chapter or two are devoted to the distribution of plants, and the occurrence of certain crops, according to the geographical features and geological conditions of the country.

Bulletin de la Fédération des Sociétés d'Horticulture de Belgique.

The volume for 1880 has lately been published. It contains, in addition to the statutes, which are, as it seems to us, seeing that they occupy so much space, unnecessarily repeated year after year, reports of the proceedings of the several federated societies, notices of the National Exhibition at Brussels in connection with the celebration of the fiftieth year of Belgian independence, the horticultural congress held at Antwerp, the *correspondance botanique*, and the notice of Brazilian Bromeliads by Dr. Wawa previously alluded to.

Correspondance Botanique.

The ninth edition of Prof. Morren's useful directory for botanical gardens, museums, professors, horticultural and horticultural societies throughout the world, has lately been issued. It is an address-book which those who have dealings with the colonies or foreign countries, as well as our own, cannot well be without—*Éloge à la Boverie!*

The Bible Educator.

Messrs. Cassell send us the first part of a new edition of this useful publication, edited by a ripe

scholar, the Dean of Wells. The articles on the plants of the Bible are from the pen of Mr. Carruthers, who begins at the beginning with *Kanunculaceæ*, and follows the Candollean sequence. The brilliant *Anemone* is considered as possibly having been the "lily of the field," while the *Nigella sativa* represents the Fitches of Isaiah.

— *Book of Sports and Pastimes*,—Messrs. Cassell send us the first part of an illustrated periodical devoted to such subjects as cricket, tennis, golf, football, and the like, which we commend to the notice of those interested.

— *May's Press Manual*, 1882.—This purports to be a complete list of newspapers and periodical publications published in the United Kingdom, with indications of the population of the various towns and counties and of the principal branches of industry followed in them. Even as we write a new candidate for insertion appears in the form of Mr. ROBINSON'S new venture, the *Farmer's Gazette*, a penny journal of large size and mixed contents, published weekly, to be devoted to the interests of the farmer.

Reports of Societies.

Bristol Spring Exhibition.—The twelfth spring exhibition of this Society was held in the Victoria Rooms, Clifton, on the 22d and 23d ult., and was admittedly the best exhibition of the kind ever held under the auspices of the Society. The general arrangement of the exhibition was excellent, as is always the case at Bristol, the centre table of the large room was furnished with tall Palms and other foliage plants, and flanked upon either side by a fine display of bulbs—the sides of the room being effectively decorated with banks of choice plants, forced flowers and bulbs, a fine display of the latter being furnished by Messrs. Garway & Co., of the Lurdham Down Nurseries, who alone set up over 300 choice named *Hyacinths* in their collection—quite a little exhibition in itself. Choice Ferns, table and room plants—the latter a very attractive feature of the exhibition—and cut flowers, made a good show in a separate room by themselves. Fruit and vegetables were not largely represented upon this occasion, but Mr. Fisher and Mr. Whitwell showed some good dishes of Pears and Apples, and Mrs. M. Miller sent a dish of early Strawberries. In class 1 (prize given by the award, Walter Derham, Esq., M.A.), for the best twenty-four *Hyacinths*—not less than eighteen varieties—and twelve pots of Tulips Mr. W. Perry, gr. to H. C. Mills, Esq., easily carried off the Silver Cup with a collection in every respect worthy the prize.

Mr. Marsh, gr. to Mr. Dunlop, Esq., was 2d, and Mr. Obmen, gr. to Mrs. R. P. King, 3d, also showing creditable collections. In class 2, for six named *Hyacinths*, distinct, gr. to W. Fox obtained 1st place. Mr. George Howe, gr. to Lewis Fry, Esq., M.P., 2d; and Mr. H. Spry 3d. Tulips were well shown by Mr. Obmen, gr. to Mrs. Fox, to Mrs. Harle, and Mr. H. K. Ward. Class 3 brought out some excellent exhibits, the Society offering a Silver Cup value four guineas for a collection of plants in bloom (Orchids excluded), arranged on a space 14 by 4 feet. Mr. Perry, gr. to H. C. Mills, Esq., secured the 1st prize. His 1st prize collection contained fine examples of *Antirrhinum Scherzerianum*, *Chorozema cordatum*, *Aphellex humilis*, *Pimelæa spectabilis*, and finished off with a neat border of dwarf flowering plants and Ferns. The other collections were also very nicely arranged. Analysis were well shown by Mrs. R. P. King, and in class 10, for the single specimen Orchid, Mr. Perry had the 1st prize for a magnificent specimen of *Dendrobium Wardianum*, Messrs. Maule & Son had the 1st prize for forced Rhododendrons, and in class 11, for ornamental foliage plants, distinct varieties, the plants of J. Derham, Esq. (W. Rye, gr.), were awarded the 1st prize, and Mr. T. Bush, 2d, both exhibitors showing good collections. For forced hard-wooded plants, Messrs. Maule & Son exhibit *Pyrus Almond*, *Ribes albanum*, *Ledum latifolium*, *Kalmia latifolia*, and *Azalea pontica*, and easily carried off the 1st prize. In class 18, for a collection of plants arranged on a space 10 feet by 4 feet, Mr. Perry, gr. to H. C. Miller, Esq., was again well to the front, his collection winning the 1st prize, and also being awarded the Knightiana Silver Medal of the Royal Horticultural Society as being the best collection of plants in the show. This collection was conspicuous for quality throughout, containing, as it did, many choice Palms, and a large proportion of well-flowered Orchids, including handsome specimens of *Cattleya*, *Odontoglossum* in variety, *Lycaste*s, and others artistically arranged, and making in all a splendid display of really choice plants. Messrs. Maule & Son obtained 2d place for a very fine collection, scarcely less interesting in appearance, but rather behind in quality, considering the large number of valuable plants contained in Mr. Perry's collection. Next in importance to awarding the Silver Medal was the task of awarding the Bronze Medal of the Royal Horticultural Society for the best twelve *Hyacinths* in any

class, No. 1 class excluded, and the post of honour was taken by Mr. George Welby with an even lot, well grown throughout, and the colours blended to advantage in arrangement. There were five other competitors or more of the collections being exceedingly meritorious in point of general culture. For four stove or greenhouse plants in flower Mr. Perry was again successful with fine plants of *Darwinia fascioides*, *Azalea trichophylla*, *Erica*, *Wendlandia*, *Dendrobium* and *Nobile*, the 2d prize going to Mr. E. Cole, gr. to W. Pettick, Esq., who had naturally trained plants, which had a very good effect. Mr. Rye, gr. to J. Derham, Esq., took the 3d prize. Special prizes were offered by many leading gentlemen of the neighbourhood, and for these there was spirited competition. For four ornamental foliage plants (prize offered by the High Sheriff, W. Edwards George, Esq.), Mr. Rye, gr. to J. Derham, Esq., was 1st, and Mr. T. Bush ad., and a prize offered by R. Hassel, Esq., for two *Azaleas* suitable for table decoration was won by Mr. Budget's gardener, who showed very good plants. The 2d prize was offered by Mrs. G. H. Ames, for six plants suitable for table decoration, not less than three distinct varieties, and 1st honours were awarded to Mr. Stevens, gr. to N. Budget, Esq., who had neat examples of *Coccos* *Wendlandia*, *Pteris*, *Polka*, and *Adiantum*; Mr. Cole was 2d, and Mr. G. Howe, gr. to Lewis Fry, Esq., M.P., was 3d, in a very good class indeed. For six stove and greenhouse Ferns Mr. Bannister, gr. to H. St. V. Ames, Esq., was in his old place with a finely grown collection, well handled and arranged, and these it need hardly be added came in for a large share of attention from the visitors, being the principal exhibit in the smaller room occupied with table plants, cut flowers, &c. Mr. Rye, gr. to J. Derham, Esq., was awarded the 2d place. Class 3t brought out a strong competition for six plants in flower suitable for sitting-rooms, and Mr. G. Howe, gr. to L. Fry, Esq., M.P., took the 1st prize, with finely grown plants of *Cyclamen*, *Lachenalia splendens*, *Mignonette*, and a model plant of *Thyrsanthus* *rutilans*. The ad and 3d prize collections, from Mr. Rye and Mrs. Hunt, were also very good, some of the plants being remarkably well grown and judiciously selected. *Azaleas*, *Clematis*, *pot Roses*, &c., were also well shown, and bouquets and devices for the dinner-table were tastefully and artistically arranged. (From a Correspondent.)

Glasgow and West of Scotland Horticultural, &c.—The spring show of this Society was held on Monday, Tuesday, and Wednesday, at the City Hall, but was not very well attended, owing to the inclemency of the weather. The principal features of the show were the *Hycacinths*, and a magnificent collection of plants sent, not for competition, by D. Tod, Esq., of Eastwood Park (gr. Mr. Ewart). This collection contained the best lot of *Orchids*, &c., I have ever seen put up by a local exhibitor out of London; they were splendidly arranged, and very much admired. The competition for *Orchids* was very good, 1st prize falling to Mr. P. Mackenzie, nurseryman, for good specimens, well-flowered, 3 feet through, of *Cologyne cristata*, *Cypripedium* *willsonii*, and a good *Meloblossum Alexandrie*, with two spikes; 2d, K. Smith, Esq., Bretherton Park, Stirling (Mr. McLeod), who had a fine *Cymbidium* *Lowii*, *Odontoglossum* *Chestertonii* and *Hullii*; 3d, J. Gordon, Esq. (gr. Mr. Hogge). This collection contained the best lot of *Orchids*, &c., I have ever seen put up by a local exhibitor out of London; they were splendidly arranged, and very much admired. The competition for *Bouquets* brought some seven or eight competitors, but good flowers were entirely spoilt through overcrowding. Some excellent bouquets were shown by Mrs. Mackenzie, not for competition. The other competitors would do well by taking a lesson from those exhibited by this lady. The amateurs' classes were well represented; some of the specimens shown reflected credit upon those who exhibited them.

Vegetables were poorly represented, but the 1st prize went to some good samples of *Peas*, *Beans*, *Mushrooms*, *Carrots*, *Cauliflowers*, &c. Messrs. Aplin & McAlister contributed a fine collection of hardy *Rhododendrons*, *Azalea indica* and *mollis*, which contained many novelties of sterling merit, well flowered. Messrs. Smith & Sissons had a good table of miscellaneous stove and greenhouse foliage plants, including *Aspidistra*, *Polka*, *Adiantum*, &c., which brought a grand lot of *Sprengs* and *Lily of the Valley*, and some nice young well flowered *Azalea indica*. (From a Correspondent.)

The Poultry Yard.

SITTING HENS.—What may be termed professional poultry-keepers, who make exhibiting fowls their main consideration, always try to have their earliest chicks hatched shortly after the new year, and during January and February, and to address any words to them at the present time would be a superfluous matter; but the great majority, who keep fowls for domestic purposes, will hardly have thought of beginning to hatch yet, and it is their benefit we have in view. Further, they may be assured that it is not yet too late to hatch prize fowls; many of ours which took high honours at the leading shows last autumn, including the September show of the British Dairy Farmers' Association, were not hatched until

April. This is an excellent time to get them out, and the present is a good time for sitting the hens. As to the best sitters, we are of opinion that all kinds are good. No hen will become broody until she has laid a number of eggs. If they do this in November and December they are almost sure to want to sit in January, and by trying to get them to lay early in this way broody hens need never be scarce from the beginning of January. However, if it is difficult to get them, they are plentiful enough now, and every one who wishes to hatch chickens should begin at once. For a day or two at first the hens may only go a short time on the nest, and if any one goes near them they may fly off hurriedly, but by putting two or three eggs in the nest, and allowing her to remain quiet for two or three days, nothing will cause her to leave it afterwards, and it is then the eggs for hatching should be put down. When a strange hen is had for hatching always let her settle on useless eggs before risking the good ones. By not attending to this we have sometimes been disappointed. Pullets are never very sure sitters at first. They may remain on the nest for a fortnight and desert it afterwards. Old hens seldom do this, and these we always secure for valuable eggs. As to the best position for the nest, it is a difficult matter to select. Generally the hen will do this, and she is a good judge. Ours are very fond of sitting under the roots of old trees, and in quiet corners in the woods, and they answer so well that we seldom remove them indoors. Some say, always keep the eggs on the ground; but few advise having the nest any great distance from the surface; and yet we have had as successful hatches from our 4-feet high nests as ever we had on the level. A repetition of this has caused us not to be very particular about the position of our hatching-nests, providing they are not likely to be disturbed by dogs, cats, or any other thing. A good quantity of straw or hay should form the nest, and the air which surrounds it should not be too dry. This, especially when hatching is taking place, protracts incubation, and is injurious to the young chicks.

We never like to set eggs which are more than ten days old, and if they are only newly laid when put under the hen, so much the better. Fresh eggs always hatch out to time better than old ones; but this depends a little on the way the hen has behaved. Close sitters with fresh eggs may have them out on the twentieth day, while those of an opposite kind may not be seen until the twenty-second day. The earlier and quicker they hatch the better are the chicks. Those over-due are always weakly, and when some hatch to-day and others to-morrow, loss is almost sure to occur, as the mother gives extra attention to those who call, and neglects the others. Many late chicks have been hatched out by us by the fireside in a wool bag. Only the other day a hen which had never brought out chicks before hatched a few, and immediately destroyed them by eating their heads off. Mothers of this kind are sometimes to be found, but they should never be used a second time, and as soon as they are fat should be sent to the kitchen. Beginners at looking after sitting hens generally give them too much attention. It is often supposed that there is some stated time they must be off the eggs daily, but this we do not look upon as of great importance. Some of our hens are off about five minutes, others fifteen, and some even more than that; but from five minutes to twenty minutes is our time, and daily as a rule, but no harm will result through their only being off every other day. In consulting poultry books on this subject, and watching the hens, much difference may be observed. Some hens which have brought strayed broods from the woods have never left their nest and hiding-place above twice weekly during the whole period, and broods of the kind are not the fewest in number or the weakest in health, as a rule.

Notes on treatment of young chickens must stand over to another number; but I may say to all, let the broody hens have as much of their own way as possible during the sitting period, and the results may be better than a continual opposition to Nature.

CHICKEN RAISING.—There can be no doubt but that there is not only a frightful mortality amongst early chickens, but it is a mortality that largely may be prevented. Two things are chiefly responsible for this undesirable result. First, hens are set in cold or unsuitable places, and the hatching process is often interfered with; hence the chickens are weakly, and in-

capable of enduring sudden chills or cold rains. I have always found it to be of the first importance that nests should be made on the ground in a slight hollow, and in a warm cosy corner. The small amount of moisture extracted from the earth in the process of incubation helps to soften the egg-shell, and to greatly facilitate healthy hatching. Sitting hens should be fed at a regular hour each morning, and should be seen again on to their nests before leaving. If the morning is very cold a piece of flannel dropped over the eggs will enable the hen to have an additional minute's run with safety. Success depends so much upon attention during the early months of the year. Late sittings, never half so valuable, may often be left to take care of themselves. If we could not only rear all the chickens hatched in March, but all the eggs set, we should have many more winter layers, and eggs would at that season be far cheaper. Of course it is well to set the eggs of regular winter layers, but then the earliest eggs must of necessity be from such fowls. A friend who has white Leghorns said that all through the winter he had been getting eight and nine eggs per day from ten hens. Of course the past winter has been an exceptional one, but still the Leghorns are without doubt first-rate winter layers. Then, secondly, after chickens are hatched they want a good warm run and shelter from cold wind and rains for a month at least; after that time, the weather becoming warmer, they can pretty well take care of themselves. It will shock some gardeners perhaps to find me advocating the use of a late vinery, in which there are no plants or stages, as an early chicken run, but it is just the place for them, and the warmth found under the glass would help them amazingly. If any one were to start chicken raising on a large scale they would find a glass house of this kind indispensable. *Dorking.*

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, APRIL 5, 1882.

MONTH AND DAY.	BAROMETRE.		TEMPERATURE OF THE AIR.		HYGROMETRIC DEGREES (from tables 6th Edition).	WIND.	RAINFALL.
	Mean Reading Reduced to Average of 48 Years.	Highest.	Range.	Direction of Mean Wind for the Day.			
Mar. 30	29.43	+0.33 57.9	17.0	15.0	47.7	4.9	W. 0.00
31	29.46	+0.35 55.5	16.0	15.5	46.0	2.0	W. 0.00

Mar. 30.	A very fine bright day, sun shining brightly. Fine night, clear and cloudy.						
31.	A fine day, sun shining brightly, blue sky. Fine night, generally clear.						
April 1.	A very blue bright morning, sun shining brightly, blue sky. Clear night.						
2.	A fine day, sky overcast from 3 P.M. Fine cloudy night.						
3.	A dull morning. Fine bright afternoon, blue sky. Fine night.						
4.	A very fine bright day, blue sky. Fine night, but cool.						
5.	A dull overcast morning. A gleam of sunshine at noon, and occasional bright gleams afterwards. A fine day.						

LONDON: Atmospheric Pressure.—During the week ending April 1, the reading of the barometer at the level of the sea increased from 29.37 inches at the beginning of the week to 30.14 inches by 9 A.M. on the 27th, decreased to 29.13 inches by 3 P.M. on the same day, increased to 29.22 inches by 9 A.M. on the 28th, decreased to 29.54 inches by midnight of the 30th, increased to 29.62 inches by 9 A.M. on the 31st, decreased to 29.05 inches by 3 P.M. on the same day, and was 29.86 inches by the end of the week. The mean reading for the week at the level of the sea was 29.85 inches, being 0.03 inch lower than last week, and 0.09 inch below the average of the week.

Temperature.—The highest temperature in the

shade in the week was 62° on April 1. On the 26th the highest temperature reached was 49°. The mean of the seven high day temperatures was 54°·3.

The lowest temperature in the shade in the week was 35°, on the 26th of March; on the 29th the lowest temperature was 40°. The mean of the seven lowest temperatures was 40°·1.

The greatest range of temperature in one day was 21°·5, on April 1; the smallest was 6°, on March 29. The mean of the seven daily ranges was 14°·2.

The mean temperatures were, on the 26th, 40°·9; on the 27th, 43°·9; on the 28th, 46°·9; on the 29th, 48°·7; on the 30th, 47°·7; on the 31st, 40°; and on April 1, 49°·1. Of these that of the 26th was 1°·6 below its average, and those of the 27th, 28th, 29th, 30th, 31st, and April 1 were 1°·7, 2°·0, 3°·4, 5°·4, 4°·2, and 4°·9 respectively above their averages.

The mean temperature of the air for the week was 46°·2, being 1°·8 higher than last week, and 5° above the average of the week.

The highest reading of a thermometer with blackened bulb in vacuo, placed in the full rays of the sun, was 130°·5 on April 1; the highest on March 29 was 77°. The mean of the seven readings was 101°·9.

The lowest reading of a minimum thermometer with its bulb placed on grass and fully exposed to the sky was 32°, on March 26; the mean of the seven readings was 36°.

Rain fell on March 26 to the amount of 0·37 inch.

ENGLAND: Temperature.—During the week ending April 1 the highest temperatures were 65° at Sunderland, 63°·2 at Leicester, and 63°·1 at Cambridge. The highest temperature at Bradford was 54°·8; at Bolton 54°·8, and at Wolverhampton 55°·4. The general mean was 58°·1.

The lowest temperatures in the week were 20°·6 at Nottingham, 30° at Hull, and 30°·8 at Wolverhampton. The lowest temperature at Liverpool was 38°·5, at Leeds 36°, and Plymouth 35°·2. The general mean was 33°·6.

The greatest ranges of temperature in the week were 32°·2 at Leicester, 30°·1 at Cambridge, and 30° at Sunderland. The least ranges were 17°·1 at Liverpool, 19°·3 at Bradford, and 20°·8 at Plymouth. The general mean was 24°·5.

The mean of the seven high day temperatures was highest at Sunderland, 58°·5, at Cambridge 57°·8, and at Leicester 55°·6; and was lowest at Bolton, 49°·5, at Wolverhampton 50°·4, and at Bradford 50°·5. The general mean was 53°·4.

The mean of the seven low night temperatures was highest at Liverpool, 42°·1, at Truro 41°·7, and at Plymouth 41°·4; and lowest at Hull, 35°·4, at Wolverhampton 36°·8, and at Leicester 37°·5. The general mean was 39°·2.

The mean daily range was greatest at Sunderland, 19°·8, at Cambridge 18°·8, and at Hull 17°; and was least at Liverpool, 9°·1, at Bradford 10°·2, and at Leeds 11°·4. The general mean was 14°·2.

The mean temperature for the week was highest at Sunderland, 47°·4, at Cambridge 47°·2, and at Truro 47°·1; and was lowest at Wolverhampton, 42°·4, at Bolton 42°·5, and at Hull 42°·7. The general mean was 45°·1.

Rain.—The largest falls were 1·22 inch at Truro, 1·20 inch at Leeds, and 1·03 inch at Nottingham. The smallest falls were 0·03 inch at Leicester, and 0·06 inch at Cambridge. No rain fell at Brighton. The general mean was 0·45 inch.

SCOTLAND: Temperature.—During the week ending April 1 the highest temperature was 59°·2, at Aberdeen; at Glasgow, Greenock, and Paisley the highest temperature reached was 55°. The general mean was 50°·4.

The lowest temperature in the week was 31°·5, at Glasgow; at Leith the lowest temperature was 37°. The general mean was 34°·1.

The mean temperature for the week was highest at Edinburgh, 44°·1; and at Leith 43°·2; and was lowest at Aberdeen, 43°·3. The general mean was 44°·4.

Rain.—The largest fall was 1·47 inch, at Greenock; the smallest was 0·15 inch, at Dundee. The general average fall was 0·54 inch.

JAMES GLAISHER, F.R.S.

Variorum.

THE DOUBLE CRIMSON PRIMROSE.—What a pity it is this exquisite gem so difficult of management! It is the queen of all the double Primroses, old and new, there is nothing in this way that can measure itself with any chance of success against its superb beauty. It is known in the North of Ireland as Madame de Pompadour, and in other places as the Crimson Velvet, and when it is seen in flower, under whatever name, and at its best, it is like a floral star of the first magnitude, attracting to itself all who have the perception of beauty in flowers. Somehow,

the plants that have been obtained from any part of the country this season are poor in appearance and dear in price. From Scotland and from Ireland alike poor examples are forthcoming. Where grown with care they establish themselves a little, and appear to be flourishing, and then a time of deterioration comes, and the plants gradually die away. The most beautiful of the double Primroses appear the most difficult to manage; the true old double purple, the fine old late golden-yellow, and the beautiful and distinct double blush are all liable to decay in the same way as the double crimson, and they are always scarce. The main difficulty appears to be to induce the tap-roots to throw out young rootlets to give added vigour to the plants; but, instead of doing this root sets in at the tap-root, and spreading upwards results in entire decay. In the case of imperfectly rooted plants the best plan is to put the plants round the sides of the pot, two or three in a pot, using a light sandy soil on a well drained bottom, pressing the soil firmly about the plants, and keeping the pots in a shady cold frame. The scarcity of the choicer varieties makes the demand large, and constant division has to be resorted to, and deterioration of constitutional vigour ensues. Happy are they who have succeeded in growing these plants into well established specimens. Sometimes one hears of places where these exist, but they are few. If some one were to rise up who could inform us how to treat the beautiful old double crimson Primrose so that it could become as common in our gardens as the double lilac or the double white, they would do a substantial service to practical horticulture. This remark would prove equally desirable in the case of other plants; meanwhile, allow a claim to be put in for a lovely hardy spring flower that is too seldom seen, but when once seen in all its rare beauty is seldom forgotten.

THE ORANGE TRADE IN THE AZORES.—In a review of the produce of the Azores, dated about the middle of last year, it is stated that the Orange trade shows indications of decline; 220,678 "malotes" boxes of Oranges, of the value of £42,312, were exported to England, and notwithstanding this apparently large number the season was stated to be a most disastrous one for St. Michael's, the Orange trade every year getting less and less, and the population emigrating because they are unable to find employment and subsistence. Several circumstances, however, have tended to circumscribe the exportation of Oranges to England; firstly, the old trees have been left, young ones have not been planted in sufficiently large numbers to replace the old ones, and a corresponding diminution of fine Oranges has been the result; secondly, a series of rainy seasons has caused the Oranges to drop off before maturity. Instead of 401,191 "malotes" or flat boxes of Oranges, which were exported in 1878 and nearly as many in 1879, only 220,678 were exported last year, being little more than half. On the other hand the anticipated falling off of the Orange trade has stimulated the cultivation of Pine-apples, which has been raised to 57,232 Pines exported during the season under review against 35,207 and 49,809 exported in 1878 and 1879 respectively. But what has tended more than anything to paralyse the Orange trade with England has been the arrival of Oranges from Valencia in Spain, and the islands of the Mediterranean. In 1872, 417,026 cases of Oranges were exported to Great Britain from Valencia, and in 1878 this trade had increased to 645,000 cases, and no doubt during the last two years the importation of Oranges to England must have been more important. It is stated further that another cause of the diminution of this trade has been the employment of steamships instead of sailing vessels, for one of these large steamers will take six times as many Oranges as the former sailing ships did, and on that score landing in England at one time, and delivering in a few weeks the whole of the Azores crop of Oranges and meeting at the same time the shipments from Valencia, the market in England became glutted, and this at a cold winter season when the state of the weather limited the consumption. In 1872 and 1873 steam vessels were purchased by a company in St. Michael's; no doubt the speculation has proved remunerative to the company, but detrimental to the interests of the proprietors of Oranges in the island and to the public generally, by depreciating the value of the Oranges from St. Michael's, for the arrival of Oranges by steam vessels could be calculated while that of sailing vessels could not, and the market rigged accord-

ingly. The prices latterly have been so low as to give cause for speculation on the advisability of some other article of export being found to replace the Orange. The Coffee tree has been tried and found to succeed very well—that is, that the trees grow very well in sheltered situations and produce fine Coffee beans, but it has still to be ascertained whether the damp climate of the Azores will allow these beans to be dried sufficiently for exportation. Great difficulty attends the drying of the Indian Corn cobs, but as in several forms one of the principal articles of food for the inhabitants and for the towns on the continent of Portugal, the difficulty has been overcome. The Tea plant has also been tried and found successful, and two Chinamen were sent for to teach the means adopted for curing the leaf, which has also to contend with the extremely damp climate of these islands. In doing so it was found that the leaf requires an immense deal of manipulation before it can be presented for sale, and a great part of this manipulation can only be accomplished by mixing up with the hands the Tea leaves. Perhaps some better way may be discovered in process of time when this cultivation comes to be better known; and in the meantime the plant thrives very well, and does not appear to require more shelter than the Coffee or Orange trees.

Enquiries.

He that questioneth much shall learn much.—BACON.

CARPENTANA CALIPORNIA.—Does this plant require a wall? *H. N. G., Milton.*

DENDROBIUM NOBILE.—In what year, where from, and by whom, was *Dendrobium nobile* introduced into this country? *A. G.* [In 1836, from Macao, an island at the south-western mouth of the Canton River, China. *Ed.*]

PRIZE MONEY.—ALEXANDRIA PALACE.—Will you please tell me what are the proper parties at the Alexandria Palace to apply to for any sum of prize-money? There seems to be great difficulty in getting it. *Exhibitor.* We presume the Messrs. Harber & Jones, are the responsible persons. *Ed.*

Answers to Correspondents.

CALVILLE APPLE. *J. H. O.* The name Calville dates from the latter part of the sixteenth century. It is, I presume, doubtful, but is probably taken from Calville, a parish in Normandy. The matter is not an old one, as is noticeable enough in Leroy's *Journalnaire de Pondichéry*, but we cannot say that any very definite result is obtained.

DENDROBIUM NOBILE. *H. L. Bromberg.* Your plants of *Dendrobium nobile* now growing freely will not flower this season, but you may reasonably expect a good show of flowers next season, on the growths made last year, provided you give the plant a good rest through the winter in a temperature of 50° to 55°. During the resting period give scarcely any water to the roots till the flower-buds appear in spring, and keep the atmosphere of the house dry. It is not necessary to repot every year, unless the material about the roots gets sour, which it will not do if you give good drainage and a good fibrous peat and moss for placing round the roots of the plants. Your plant is too far advanced in growth to repot this season without giving it a decided check. Pick some of the old material from about the roots, and top-dress it with a mixture of equal parts fibrous peat and sphagnum moss, taking care not to place it in too close contact with the young growths.

INULUS. *F. Furzebaker.* A careful microscopical examination of the pieces of *Inula* roots has clearly disproved the existence of the *Phyllaria* upon them. We only found *Inula*, *S. Asplenium*, and *Phyllaria* the bark, such as is generally found in diseased vegetable structures. *L. O. H.*

LAURELS. *J. E.* In all probability the leaves were covered with drops of water, which when the sun's rays poured upon them, acted as burning glasses. We never saw quite so bad a case before.

NAMES OF PLANTS. *Mrs. Leigh, Berberis Darwinii, E. & J. Perkins.* A form of *Rhododendron arboreum*, which goes by the name of *R. cammoneum*, and which is much harder than the true scarlet *R. arboreum*, and distinguished from it by the colour of the flowers and deep brown tomentum on the under-surface of the leaves. It is frequently to be found in collections, its hardness having preserved it where others have failed. *J. H. M.—R. R. Adiantum bispidulum*; 2. *Selagin pubescens* (S. Braun, Baker); 3. *Adiantum concinnum*; 4. *A. macrophyllum*; 5. *Callipteris anbigua* (Malabarica).—*Saxifraga, Haldersonii*; *Saxifraga Poultonii—K. & S. Asplenium bibratum* (L. sectum). There should be on the plant some fronds with broader less cut panicles.—*H. L. E. 1.* double flowering Peach; 2. *Spiraea alba*; *rodifolia* variety; 3. *Ribes Beatonii*; 4. *Aspidistra*; *S. angustatum* and *R. aureum*; 4. *Leontis* daisy. Never send specimens packed in cotton-wool, damp blotting-paper, or still better, damp moss, is far preferable.—*H. E. R.* Your plant is correctly named, *Praxina Goldiana*.—

STOCK KEPT IN LONDON at Arch 92, Spitafields Station, Bethnal Green, E., and Machines may be ordered from any respectable Ironmonger.

Ransomes, Head & Jefferies, ORWELL WORKS, IPSWICH.

THE "AUTOMATON."
SIZES, 8 to 24 inches.
THE BEST GENERAL PURPOSE MACHINE.

The "AUTOMATON" Lawn Mowers are thoroughly strong, well-made, and durable machines, and the best suited for general work and *Gardener's* use. They cut the grass perfectly, leave no ribs, but produce a smooth velvety surface on the Lawn, and are light as draught.

The "AUTOMATONS" have front rollers for general work, and *side* rollers for cutting long grass, or when it is necessary to roll the grass in front of the cutters. They have the best machine made gearing, the best self-sharpening knives of steel and iron rolled together, and automatic silent drivers.

R. H. & J. also manufacture "REVERSIBLE" Lawn Mowers for Small Gardens and Borders, and "HORSE-POWER" Lawn Mowers for Large Lawns, &c.

THE "WORLD" (the "GLOBE") Lawn Mowers are intended for cutting long grass; and, whilst similar to the Lawn Mowers imported from America, have the special advantages of the more accurate fitting and general durability of English manufacture and perfect adjustment.

The "WORLDS" will cut wet, dry, long, or short grass without clogging, and cut off almost all the "hairs." They leave the surface smoother than similar machines, and are well adapted for getting over a large amount of work with little labour.

SIZES, 8 to 24 inches. FOR CUTTING LONG GRASS.

RANSOMES' LAWN MOWERS ARE THE BEST.
MELBOURNE EXHIBITION, 1881. THE HIGHEST AWARD.

EPPS'S
COCOA
GRATEFUL
AND
COMFORTING.
Made simply with boiling water or milk. Sold only in packets, labelled, JAMES EPPS AND CO., HOLOWAY PATENT CHEMISTS, LONDON.
Makers of Epps's Chocolate Essence for Afternoon use.

HOLLOWAY'S PILLS.—This purifying and regulating Medicine should occasionally be had recourse to during foggy, cold, and wet weather. These Pills are the best preventive of headaches, sore throat, quins, pleurisy, and asthma, and are sure remedies for constipation, indigestion, and inflammation. A moderate attention to the directions folded round each box will enable every invalid to take the Pills in the most advantageous manner. They have been taken by the most delicate, and the circumstances under which they must be increased or diminished. Holloway's Pills act as alteratives, aperients, and tonics. Even when these Pills have been taken to the last resource, the result has always been gratifying. Even when they fail to cure, they assuage the severity of the symptoms, and diminish the danger.

SEND FOR A PRICE LIST OF

JOHN BLAKE'S PATENT SELF-ACTING HYDRAULIC RAMS

For Raising Water for the Supply of Towns, Villages, Irrigation, Railway Stations, Mansions, Fountains, Farms.

Jackson, Esq., Maclesfield. E. H. Nicholson, Esq., Beech Hill, Londonderry.

TESTIMONIALS.

From Colonel TREMAYNE, Carlew, Ferran-a-Worthal, Cornwall, March 7, 1880. "The Self-acting Hydraulic Ram erected here about two years ago is, I am pleased to say, working most satisfactorily, sending up water at the rate of 2000 gallons per day to a height of 125 feet, and a distance of more than 2000 yards. The quantity of water is as much as you undertook to deliver."

From Major J. FINCHER TRIST, Tristford, Harberton, South Devon, September 29, 1880. "I have much pleasure in informing you that the Ram and Fire Extinguishing Apparatus, with about 2 yards of service pipe, which your men have here, give me the greatest possible satisfaction. From the first till now there has been no hitch whatever, and I do not at all anticipate that you will ever be troubled with any stoppage of the water, and I am glad to hear that you can draw off the chimney a powerful jet of water, which is brought down in a 4 inch bore pipe from the service tank, holding upwards of 20,000 gallons, at an elevation of 2.5 feet, to which your Rams force the water very much in excess of the quantity you guaranteed. I have already recommended you to others in war, and hope to continue to do so."

From the Right Hon. T. SOTHERN ESTCOURT, Estcourt Park, Gloucestershire, September 6, 1875. "You will be glad to hear, as I am to tell you, that your Self-acting Hydraulic Ram has worked exceedingly well and continuously since it was erected, more than twelve months ago. It is, in fact, perfectly successful."

(The following is a copy in the above case of 2400 feet long, with 100 feet rise) From L. HANMER, Esq., Deanwater, Wilmshole, November 20, 1873. "Dear Sir,—In answer to your enquiries respecting the Hydraulic Ram you supplied me with six months ago, I beg to state that I am more than satisfied with it. It has done its duty, sending up to the top of the house 500 gallons of water in twenty-five hours, whereas you only undertook to deliver in that time 200 gallons. I have therefore every reason to be well pleased with your work, and am especially so. I had a ram supplied me by another maker, which could not send up a single gallon of water to the height required, and a second and inferior one that no man with a fall of a feet could send up water to the distance required, namely, 120 feet. But yours is an accomplished fact, and does its work most effectually."

From JOHN ROWE BENNION, Esq., Nursted House, Petersfield, August 25, 1880. "I have much pleasure in saying that the two Hydraulic Rams you put down for me and which are supplied from a spring, now yielding in this dry season, only 3 gallons per minute are sending up an ample supply of water to my house and the home farm, discharging the supply through more than 200 feet of pipes, and to an elevation of 137 feet. Of this result, I think you have as much reason to be proud as I have to be satisfied."

From Colonel STARKIE, Lovely Hall, Blackburn, May 13, 1878. "Sir,—I have great pleasure in testifying to the good qualities possessed by the Ram you erected here last year. It has done its work well and is as perfect as the other Ram did, which was of a different construction, and supplied by a different firm. I consider that there are great difficulties to contend with here, but your practical mechanical knowledge, both as to the construction of the Ram and its situation here, overcame most of the difficulties that we had to contend against."

From W. SCARTH, Esq., Agent to His Grace the Duke of Cleveland. "The Hydraulic Ram you supplied to his Grace the Duke of Cleveland, in 1875, is a complete success. It worked for more than two years without once stopping, and throws more water than promised."

From R. SMITHURST, Esq., Ellerbeck, Chorley, January 13, 1877. "Sir,—Blake's Hydraulic Ram works as well as it did from the first. I cannot at this moment remember how many years it is since I put it up, but it must be eight or ten, and it has served my purpose admirably. It is at work almost every day, and in dry weather day and night frequently. It requires no skill to keep it right."

From G. REDMAYNE, Esq., Brathay Hall, Ambleside, January 15, 1877. "Sir,—In answer to your application respecting Blake's Hydraulic Ram, I am happy to say that so far it has been a complete success, and at a very trifling cost for repairs. It has been a great boon to me, other well-known Rams having failed, and we fell back upon Blake's as a last resource."

JOHN BLAKE, ENGINEER, ACCRINGTON, LANCASHIRE.

GRASS SEEDS

FOR LAWNS.
 Of the finest close-growing Evergreen kinds, 1s. per lb. Special preparations for all purposes, soils, &c. situations. Advice gratis.
Unsolicited Testimonials:—
 "Knowing how difficult it is to obtain pure stocks of grass seed, even when price is a secondary consideration, I write to say the supply obtained from you for our new terrace lawns has given the greatest satisfaction.
 "Please send me three bushels of the very best Lawn Grass Seeds, suitable for an exceedingly hot inland soil ... The seed I have had of you has been the only kind which has been able to resist the influence of the sun and drought upon my lawn, gravely so."

FARM SEEDS

Of all kinds, which have given unqualified satisfaction. See Illustrated and Descriptive LIST, free on application.

CAUTION.—It having come to our knowledge that some unprincipled persons have been substituting other Manures for Clay's Fertiliser, we beg to state that we guarantee the genuineness of none except in our bags, marked:—

SATURDAY, APRIL 15, 1882.

A FEAST OF PRIMROSES.

LESS than 20 miles from London, and near to the great highway to the West, lies a fine park that is bounded on its northern side by a copple, through which runs a broad green drive, and all along its length of over a mile we saw the other day a marvellous show of the British Primrose. We really fear to indicate just where this charming sight is to be found, lest those floral hawks who sweep from off the face of Nature all the flowers that come within reach should deface and despoil this tract of natural beauty. Perhaps some of the abundance of Primrose wealth seen here is due to the fact that the enclosure is a game preserve, and the stalwart keeper, robed in the customary suit of velvet, who met us with a suspicious and enquiring look, became for the nonce, not an agent of the detested Game Laws, but rather a beneficent guardian of this charming floral preserve. Here and there the Primroses ran out from margins into huge masses even of an acre in extent, preventing a perfect floral carpet, whilst here and there a stray and somewhat precocious Jubbell or a bright-coloured Ragged Robin not only gave varied hues of colour but foretold of the further beauties that are to follow.

Even here, where not a Cowslip, Oxlip, or Pteris of any kind is to be seen, there may be found some evidences of the Polyanth tendency which is so strongly manifested in cultivated Primroses. But what is of more interest is the very varied forms and outlines found in the flowers. Some—not many—but still some have flowers that are nearly round and smooth edged, and in most cases still farther they have that florist's fancy, a thrum-eye; and yet this thrum centre is no arbitrary fancy after all, for between the pin-eye and the thrum-eye there is a wide disparity—the first means coarseness and lack of finish, the other means perfection and refinement. More than that, there is a very important physiological difference which florists have hitherto too much overlooked, and which is of far greater consequence than the mere appearance. By way of contrast to the better forms are many flowers the petals of which are little better than mere floral strips, very loose and starchy, and looking very much as the British Primrose might have been in the days of the Druids. From out of some flowers the style would project an eighth of an inch, and in others it was half-way down the throat, the anthers yet lower still, so variously placed are the organs of fertility in these wild flowers.

There is, perhaps, a natural and instructive desire arising in our mind to see growing in this delightful woodland some of the rich coloured Primroses now not so very uncommon in gardens. If these were planted, and let alone, the patches of colour thrown up would indeed be varied and pleasing. But even supposing that these garden kinds would thrive under such rude culture, the crossing on to the wild pale yellows that would result would soon convert the bulk of the flowers from their

pleasing and pristine hue into dull washy reds or shades of the most inconspicuous and unpleasing kind. Probably it is far wiser to let well alone in this respect, for attempts to gardenise in Nature's haunts have seldom turned out to our satisfaction. After all, the great distinction which exists between wild and garden flowers serves perhaps more than anything else to maintain the delicious and welcome contrasts that should ever be found in cultivated and uncultivated spots. As it was close upon Eastertide, one of the great festivals of the Church, some score or more of children were busy gathering the pale Primrose flowers, putting them into neat bunches, that they might assist in the decoration of churches on Easter Day. There was enough, and to spare, for the flowers were countless, and on that head we find no cause for complaint.

If flowers at these seasons really become emblems of religious belief, stimulate gratitude and worship, there is nothing more to be said. Perhaps these Primroses, the spring Lilies of our woods, present to the minds of some more fitting offerings at religious shrines than their own hearts, because they are at least pure, and, as divine witness has been borne, are more acceptable than was Solomon in all his glory.

To pass from the bebedecked column, the goiaded roof, the rich and sparkling painted windows, the gaily dressed assemblage, and the proud swell of the organ, to the hospital where the sick and sorrowful, the poor and the needy lie racking in pain, enduring perhaps agonies indescribable, or wasting away by slow and insidious disease to inevitable death seems to be a natural psychological sequence, though scarcely a harmonious one. Seeing this wealth of flowers, and thinking of the many many hearts that but a few sweet flowers might be made to gladden, we are again rejoiced to remember that many loving, unselfish people remember the sick and the dying, and strive to bedeck their mean little chambers or cheerless looking dormitories with flowers, sweet, fresh, and beautiful. Somehow, too, there crop up recollections of the story about the cup of cold water, and we pass slowly away from our feast of Primroses, thankful in the recognition of the good that is or may be effected in the world by these humble Primroses in more than one way.

RHODODENDRONS AT KEW.

THE magnificent *R. Griffithianum* (syn. *Aucklandii*) is now in bloom in the Temperate-house, Kew. Although the flowers are not so fine as they were last year, yet every lover of the genus should visit this very beautiful and now uncommon species. In bud the florets are of coral-pink, then, gradually paling, they swell as large as hen's eggs, and finally fall open into exquisite cups of the most delicate pink, glowing white and whiter hour by hour. The style is of ordinary length and size, with a greenish stigma, but the stamens are curiously diminutive for so large a flower. This fact makes it interesting to remark that the flowers of this plant proved last year almost, if not quite barren when fertilised with its own pollen, which Mr. MANGLES found to be potent, nevertheless, on other Rhododendrons. When the species first flowered in Europe similar anomalies were remarked, and it was for a time supposed that the large-flowered variety never matured pollen at all. Here then is a species which deserves the notice of naturalists. Is it approaching a climorphic condition? Mr. MANGLES has been for two years and more experimenting with it. The Lawson Company, of Edinburgh, have already shown many very beautiful hybrids derived from it. The foliage is as grand as the flower, and the young shoots, of the richest green, are hung around with caducous crimson bracts, the brilliancy of which we leave to the *Horribians* to explain. In the same house there is also in bloom the most gigantic and beautiful hybrid *Rhododendron* we have ever seen. The truss is of enormous proportions. The plant is either a very fine specimen of *R. Broughtonii*, or a seedling of the same strain.

New Garden Plants.

LELIA LEEANA, n. hybr. (?)*

A FINE thing. At first sight I thought of *Lalia* and *Cattleya Dormaniana*; but both the short rather timid furrowed shining bulb, and the flat spreading flower colours suggested *Cattleya superba*, while the column top made me think of *Lelia pumila*. As to the perfume, which is rather powerful in *Cattleya superba*, I cannot speak about it in this novelty, the weather being very cold, and the perfume of flowers being subject to changes from time of the day, age of the flower, and individuality. My flower is rather scentless. I have no experience, however, of the two mentioned species growing together, and if any of the readers of these columns could give some evidence about this it might prove very useful. The stellate rather narrow sepals and petals are of a fine rose colour, as in a very fine *Cattleya Harrisoniana*. The lips of the purest white, the tips of the lateral laciniæ, which lie on the broad obovate middle laciniæ, are of the finest and warmest purple. There are veins of the same colour running forwards under acute angles on both sides of the middle line between the lateral laciniæ, but they do not extend far. The column has purple eais, a fine purple border to the stigmatic hollow, and a like more pallid wash at the inner base. Pollinia four, with an emarginate back, showing two bodies cohering, and the caudicula cohering on both sides. Though it is said to have lost its original beauty, after having flowered nearly three weeks, I am very satisfied with it, and think it a novelty. The *pâte de resistance*, indeed, is the lip. I feel very pleased to inscribe the plant to one of the most excellent orchidists of our era, the lucky possessor, Mr. W. Lee, Downside, Leatherhead. May this gentleman never be infected by that abominable contagious disease, the *Orchidophobia*. *H. G. Rehb. f.*

ODONTOGLOSSUM SANDBERIANUM, n. sp.

I have before me a fresh raceme, forwarded by Mr. Geo. Marriott, of Upper Edmonton, who had it from Mr. H. Gaskell, of Wootton Wood, Liverpool. I have great pleasure in seeing this fine thing, which very nearly fills the place of *Odontoglossum nevadense*. Not much is to be added to what has been stated before. The bulb is compared to that of *Odontoglossum Lindleyanum*. The lip is not quite pure white, but has a most delicate hue of lightest sulphur. There is a fine large purple-crimson mark between the callus of the lip, and there are a few small spots of this colour in front. The base of the lip consists of two short low upright lobes, and the blade is large, nearly pentaurate, acute, wavy. Sepals and petals lanceolate acuminate, light ochre, with brown marks and stripes, much as in *Odontoglossum anastratum*. Column strong, trigonous, with upright cat's-clawed wings and an abrupt prominence under the stigmatic hollow, yellowish on the top, white on the base, with some purple spots.

It is astonishing how easily some plants develop their flowers. Hence, we may expect a fine development of this species, hence I am not quite persuaded that it may not develop panicles laden with hundreds of flowers. Several of my last letters speak of the plant, and one of my correspondents says it beats *Odontoglossum nevadense*. As to this it is a matter of taste, and till now that species stands unique in the surprising heart-shaped base of its lip. *O. Sandberianum* is finely Hawthorn-scented. *H. G. Rehb. f.*

LEEA AMABILIS, Hort. Veitch.† (Fig. 77.)

The plant shown under this provisional name by Messrs. Veitch at a recent meeting of the Royal Horticultural Society promises to be one of the most beautiful of stove foliage plants. In a small state the

habit is good, and probably by suitable cultivation the compactness it now has may be retained, otherwise the natural habit of the plant would suggest that in the adult condition it may become somewhat straggling. The stems are cylindrical or sub-angular, somewhat fleshy, marked with circular cicatrices. The alternate unequally pinnate leaves are borne on long channelled leaf-stalks, from whose sides emerge at the base large leafy stipules. The pinnæ or leaflets are in two or three pairs, each leaflet shortly stalked with a minute stipel; all are more or less lanceolate, rounded at the base, acute, or even acuminate at the apex, sparsely saw-toothed at the margin, with glandular serratures. The upper surface is of a velvety texture and deep bronzy-green colour, with a rather broad central white stripe, irregularly indented at the margin. The lower surface of the leaves is of a claret-red colour, with a few thinly scattered hyaline globular glands and a central translucent green central stripe. The midrib is sharply prominent, like a knife-edge on both surfaces. The young leaves are of a bright but pale pinkish-brown colour, bent downwards, the individual pinnæ being folded in the middle (conduplicate). A figure of the plant was given in the *Journal of Horticulture* for April 6.

The *Leeas*, to which genus this plant has with great probability been referred, are shrubby or half scandent Asiatic shrubs, closely allied to Vines, but destitute of tendrils, and having pinnate foliage. There are some minor differences in the flowers and fruit to which we need not refer. The plant above referred to was collected in the journey undertaken in Borneo on behalf of Messrs. Veitch by Messrs. Burke and Curtis. It would be acceptable if these gentlemen, or one of them, would favour us with a note as to the climatal and other conditions under which the plant grows. *M. T. M.*

POLYSTICHUM ACROSTICHOIDES GRANDICEPS, n. var.

This is a very handsome variety of the well-known North American *Polystichum acrostichoides*, in which all the fronds, including the fertile ones, are multiply-branched and neatly crested at the apex, while the pinnæ are more or less distinctly dilated, or in some instances multiply parted at their apices, much in the same way as occurs in the smaller fronds of *Lastrea Filix-mas cristata*. This alteration of the normal form has, in the examples before us, in great measure obliterated the auricle which occurs at the anterior base of the pinnæ in the typical plant. The fronds reach the height of from 12 to 15 inches, or nearly that of the normal form of the species, and, like it, are of evergreen character, so that it will make a welcome addition to the hardy Ferns already in cultivation, the dimorphous nature of the fronds giving to it a distinct and well-marked character. Our knowledge of the plant is derived from specimens which have been obligingly sent to us by Messrs. W. & J. Birkenhead, of the Fern Nursery, Sale, near Manchester, who have from time to time sent us some very interesting forms both of native and exotic Ferns. We believe it was received by them amongst Ferns from North America some three years ago, and that they have been able to propagate it.

We do not find any mention of such a variety in Professor Eaton's recently completed *Ferns of North America*, a handsome, well illustrated, and valuable work on the Fern flora of that great country, so that, like most other crested varieties of Ferns, it might probably be traced to a solitary sport from the usual condition of the plant. *T. Moore.*

OCTOMERIA COCHLEARIS, *Rehb. f.* (*Supra*, 1881, p. 266.)

Ah those Orchids! Never trust them! Dr. Wallace having kindly given me a plant, it has now flowered under Herr Donat's care. Most accidentally it has not a single hair on its lip, whereas the flowers of 1880 had it covered with them! *H. G. Rehb. f.*

CATASETUM FILETUM, n. sp.†

A curious species comparable to *Catasetum cernuum*. It has rather large flowers, comparable to those of

* *Lelia Leeana*, n. hybr. (?) — *Pseudobulbo cylindrato* 2-minuticulis sulcatis monophyllis; foliis planis cuneato-oblongis, lobis usque valde concavis; floribus (sine spatula), sepalis tepalibus paulo unilatis ligulatis acutis, expansis, stellatis; labelli trilobis, lobis lateralibus semitrilobis, anterosum acutis; creta columnam rotatis et apertis sine in forma mediata obovata plana mucronulatis; columna utriusque alula accurisignate ligulata; alulae (tepala subterrata angulo subulata). *Forsk. & Groll. Leea*. — *Orchidarium collectivum intelligitibus* accerium magno cum gaudio ducta. *H. G. Rehb. f.*

† *Leea amabilis*, Hort. Veitch. — *Fruticosa glabra; foliis puberulis imparipinnatis, segmentis petiolulatis lanceolatis, basi*

rotundatis, glandulose-serratis, acuminatis, nervis, anero-ventrisibus velutius medio foveis albida lateraula tenatis, deorsum vixus glandulis parvis hyalinis conspersis, sursum medio utrinque prominente. — *Stipulis magnis foliis acutis integris petiolo longissimo superne cancellatis basi cordatis*. — *Leea*, agrost. — *Ex Borneo apterovegetant donum*. Burke et Curtis. *M. T. M.*

— *Catasetum filetum*, n. sp. — *Sepalis ligulatis acutis; tepalis oblongis acutis; labello transverso subtrilobato obtusis-angulo amplissimo in eorum obtusum rotatis, columna apice longe rostrata; basi cirata*. — *Ex Venezuela imp. ci. Linden*. *H. G. Rehb. f.*

Catasetum Naso. Sepals narrow, light reddish. They may, however, have been green before, as sometimes is the fact from withering. Petals broad, oblong acute, white. Lip a wide nearly obtuse-angled expansion descending in a blunt cone, white. Column with a very long beak and two cirrhi. This interesting species was introduced from Venezuela by Director Linden, and flowered by the Compagnie Continentale d'Horticulture, Société Anonyme, Gand. *H. G. Rehb. f.*

CATA, with double flowers of a pale rose colour. The tree is of more robust character than the preceding, with stouter branches and larger flowers, the flower-buds rounder and not so pointed as in *P. floribunda*.

P. SPECTABILIS is another variety of somewhat robust habit, with rounded flower-buds and shell-like incurved petals of a deep rose colour. This, again, is one that can hardly be too widely spread.

flowering shrubs too seldom seen. Its bushy habit, neat, small, lanceolate leaves, and profusion of small Peach-like blossoms, are very acceptable.

RHODODENDRON CHAMÆCISTUS.—Mr. Burbidge sends us from Dublin the pretty little *Rhododendron Chamæcistus* with small ovate acute shining green chilate leaves, and terminal tufts of regular lilac open bell-shaped flowers, that remind one of a *Kalmia* without its pouches to retain the stamens.

FIG. 77.—*LEEAMABILIS*: STOVE FOLIAGE PLANT. (SEE P. 492.)

FLOWERS IN SEASON.

A CORRESPONDENT sends us flowers of the lovely *PYRUS (MALUS) FLORIBUNDA*, which, if not the finest, at any rate is in the fore rank of ornamental spring flowering trees. Its long slender branches are crowned with umbels of flowers on long graceful stalks, with ovate pointed flower-buds of an intense rose colour, fading as the flowers expand. There is no reason that we know of why this most lovely tree is not more generally planted. It may be grafted, like other Apples, on the Doucin or Paradise stock.

Scarcely less beautiful is the *PYRUS MALUS BAC-*

P. MAULEI, a species we had the honour to introduce to the notice of horticulturists in June, 1874, p. 757, justifies all we said in its praise, its profusion of orange-red flowers form an agreeable variety with the old *P. japonica* and its varieties. At the time of publication it was stated by some who had not had our opportunities of judging to be a mere form of that old favourite, but we think no one seeing the two plants together would consider them as belonging to the same species now-a-days, whatever they might have done in prehistoric times.

AMYGDALUS NANA is one of those old-fashioned

ANEMONE BLANDA AND *A. APENNINA*.—Another correspondent enquires as to the distinction between these two, which indeed is not very obvious when the two are seen apart. The main difference lies in the seed-pods, that of *A. blanda* having a shorter style. Our plants both of *A. blanda* and of *apennina*, growing for years in an open border, are becoming paler in colour year by year, perhaps in afright at the slugs, which punish these little gems in a disheartening manner.

TULIPA SILVESTRIS.—Another correspondent sends us flowers of the elegant *Tulipa silvestris*, the

graceful nodding yellow flowers of which are but rarely produced, and when produced, rarely open, but their elongated oval-pointed form and clear yellow colour are very attractive. The elegance and grace of this plant form a marked contrast to the great tubular and gaily coloured of the garden Tulips, and of some of this country.

The Herbaceous Border.

...with the Emulinary, but ... bloom. It is stated to be naturalised in many places, and our correspondent speaks of it as ... abundance as to be a nuisance! The ... most flower lovers ... Probably, by ... produced to flower ... why it is ...

... very blue, is always ... need not be without ... associated with *Franula rosea*, which we find does so much better in the open border on cool stiff moist soil than in pots, forms a pair that can hardly be rivalled.

NOTES ON ANNUALS.

As this is the time of year for sowing annuals, the following notes on some ground last year may be of use as relating to some species not commonly grown. The first list were treated as half-hardy, and raised in heat about the middle or end of April, which proved to be too late for some of them. The following were good:—

- Cornus laponensis*.—Of a rich purple colour, like a small *Dahlia*; a late bloomer, and very useful for cutting.
- Emilia sagittata* = *Cacalia coccinea*.—Very bright orange-scarlet.
- Nicotiana glauca*.—Good, both as a foliage and flowering plant.
- Schizanthus luteus*.—Very pretty, but blooms late, and should be sown early.
- Tugetes pigmentifera*.—A very good strain of French Marigold; forms a brilliant edging for bedding.
- Tugetes Purpurea*.—Large single bright yellow flowers, and pretty foliage; not very free blooming in rich soil.
- Zinnia elegans*.—Brilliant yellow, and having a spreading habit, is well adapted for bedding. Lasts long in bloom.

The following were poor, and not worth growing:—

- Arabis crotocarpa*.—Coarse, and not free blooming.
- Cupressus comata*.—Very dull coloured.
- Mitella meadia*.—Flowers very small, and dull red; habit unkind and leafy.
- Pedot. Nuttallii*.—Poor and insignificant.

The following were evidently sown too late, and never bloomed:—*Martynia fragrans*; *Pharlitis Huberi*; *Seyphanthus elegans*.

Of hardy annuals which were sown where they were to grow in the borders, the following were the most satisfactory:—

- Antirrhinum album* (Yellow Sultan).—A beautiful plant, which, though very old, is not often met with in these parts; one of the best yellow flowers for cutting in show.
- Argemone grandiflora*.
- Barbarea vulgaris* (Pink Hawkweed).—Very pretty and easily grown.
- Caltha rosea purpurea*.—One of the best yellow annuals, with double pointed flowers, and good habit.
- Caltha rosea Drummondii*.—Clear yellow flowers, but not so free as the old *C. rupestris*.
- Campanula medium-plata*.—Very effective and curious.
- Campanula rotundifolia*.—Another good yellow Composite.
- Campanula rotundifolia*.—Very neat habit, and free blooming; flowers deep purple.
- Campanula rotundifolia*.—Charming plant, the orange lip as bright as a spark of fire.
- Centaurea jacea*.—Large yellow flowers, and very free. (I think this was raised in heat.)
- Phlox paniculata*.—Very neat and pretty.
- Sphacelium sphegodes*.—One of the best annual Composites.

I have mentioned the above because most of them are not very commonly grown. There are, of course, many other equally good annuals which are too well known to mention. Although I yield to none in my love of hardy perennials, yet I cannot but think the annuals are quite as pretty and interesting, and do not deserve the neglect into which they have fallen of late years.

I may add that I was very successful last year in raising perennials from seed—many of which bloomed in the same year. I wish these would be useful, I think, to all. All of O. Walker.

MERTENSIA.—The Oyster plant, *Mertensia maritima*, which owes its English name to the oyster-like taste of the leaves, is now, as far as I have been able to ascertain, an extinct plant on the Welsh coast, where it was formerly common. Miss Jekyll, of Munead, kindly gave me two plants two years ago, and it behaves in cultivation in a most exemplary manner. I planted one upon a rockery, the other in a well drained flat border, mixing sand and fine gravel with the soil, and covering the surface as far as the shoots extended with small pebbles. Both have done equally well, and ripened seed in great abundance; the seed, if left where it falls, comes up freely in the spring, but as fast as ever the shoot appears it is eaten off by slugs—the worst enemies of all the Mertensias—so that the seedlings are difficult to rear. The shoots, taken off in spring, when 2 or 3 inches long, will strike, but not readily. It is an interesting and distinct plant, and always attracts notice. *Mertensia virginica*, the Virginian Cowslip, is now in full flower, being nearly a month earlier than last year. It is imported in abundance from America, and seems to suffer nothing from its voyage, for some imported plants planted in December are now flowering well. It seems to thrive in any sheltered spot in moist rich soil. There is another imported Mertensia, called *paniculata*, which I have tried several times, but have completely failed with it. As I have never seen it doing well, I do not know what its requirements are, and should be glad of information. I have one more to mention, *M. sibirica*, easily grown, either from seed or divided plants, if the slugs can be kept from it, but they will come through soot and fine soil. In habit it resembles *M. virginica*, but is a coarser plant; the flowers are much smaller, and come out more than a month later. It is no great acquisition for ornament. C. Wolley Dod.

HEPHEROCHIRON CALIFORNICA.—The lovely little plant which bears this name is correctly figured and described in the spring catalogue of Mr. Ware, from whom I bought it in autumn. The whole plant is not 4 inches across, and it produces a long succession of flowers in abundance, borne on short stalks from the centre of the plant. In my plant they are pure white, with a black stripe up the middle of each of the six petals. The flower is something like that of *Sanguinaria canadensis*, but opens better and lasts longer, and, what is no small merit this weather, endures frost bravely, for though the flowers of *Primula rosea* and the alpine *Auricularis*, and many other plants, are quite spoilt by the severe frosts of Thursday and Friday nights, those of the *Hesperochiron* are entirely uninjured. It seems quite happy in an exposed situation on a well drained peat bed. C. Wolley Dod.

THE COMMON DOUBLE DAFFODIL.—It seems to be still a popular belief that the large double *Daffodil* of English gardens is nothing but a double form of the wild *Daffodil*, which occurs in meadows and copses in nearly every English county, and that if these single *Daffodils* are transplanted to a garden they become in a year or two common double *Daffodils*. Those who believe this should try, as I have done for many years, to make a double *Daffodil* out of a single one, and if they succeed they will have performed a difficult feat of gardening. It may be interesting to these persons to be told what is known of the history of the double *Daffodil*, which is now to be found in orchards or gardens in every corner of the kingdom. John Parkinson, an "apothecary," who lived in London, published in the year 1629 a book on gardening called *Paradiis in sole paradisiis terrestribus* (The Paradise on Earth of the Paradise which is in the Sun). With the exception of Gerard's *Herbal* this is, I believe, the oldest work on gardening in the English language. This work was published nine years after the first appearance of the common double *Daffodil*, of which he gives the following account, calling it "Pseudonarcissus Anglicus maximus"—Mr. Wilmer's great double *Daffodil*." First we have a description of the semi double and full double forms, so accurate as to leave no doubt about the identity of

the variety. Then we are told that "we had this variety first from Vincent Sion, borne in Flanders, dwelling on the Banke side, an industrious and worthy lover of faire flowers, who cherished it in his garden for many years without the hearing of any flowers until the year 1620—that having flowered with him (and hee not knowing of whom he received it, nor having ever seen the like flower before) he sheweth it to Mr. John Franqueville, of whom he supposed he had received it (for from beyond sea he never received any), who finding it to be a kinde never seen or knowne to us before caused him to respect it the more, as it is well worthy. And Mr. George Wilmer, of Stratford Bow, Esq., in his live time having likewise received it of him, (as my selfe did also) would needs appropriate it to himself if he were the first founder thereof, and call it by his owne name, Wilmer's double *Daffodil*, which since hath so continued." This *Daffodil* is still called in the Dutch catalogues Van Sion, after the name of the founder. Modern florists, especially that prince of *Daffodil* growers, Mr. Peter Barr, have tried to refer this double *Daffodil* to some existing single form. It will be observed that Parkinson calls it "*Anglicus maximus*," and says that it only differs from the double of the English wild *Daffodil* in size. Until lately it was identified with the *Pseudo-Narcissus* major, supposed to be a native of Spain. About four years ago Mr. Peter Barr obtained from Florence bulbs of a large single *Daffodil* which grows wild in the valley of the Arno there. This seems to come nearer to the single form of our common double *Daffodil* than any variety yet found. C. Wolley Dod.

NARCISSUS CERNUUS PLENUS AND N. MONTANUS.—Out of about eighty varieties of *Narcissus* which have flowered, or are flowering, in my garden this spring, the double variety of *N. cernuus* is one of the prettiest and most attractive. It is not a new plant. I saw it some years ago in a garden at Windemere as happily established in clumps, and flowering as freely, as the common double *Daffodil*. The owner gave me a few bulbs, but I am sorry to say that their increase is slow, as the *Daffodils* of this class want a warm soil. It is one of those doubles which generally assume the form in which the doubling is contained inside the tube, which remains unbroken, as in the double of the wild *Daffodil*. The only exception I have seen to this was the first flowering after transplanting, when one or two produced full double flowers; but I dare say this habit varies in different soils. Another fine variety of this class is *N. cernuus elatus*, which I bought some years ago as *cernuus Leedsii*, but which seems to have changed its name. The pure white *Narcissus montanus* may also be mentioned as one of the prettiest of the late-flowering *Daffodils*. It must be planted in light, warm, well-drained soil; for, though it is a very old variety in English gardens—older, in fact, than the common double *Daffodil*—it has never become common owing to its delicate constitution. Parkinson classes it with the *Incomparabilis* section, and tells that nothing is known of its native place, but by "the name it carries it should seeme to be bred in the mountains"—probably true, for the only place where I have ever seen it really vigorous and increasing rapidly is a garden amongst the mountains of Denbighshire. C. Wolley Dod, Edge Hall, Malpas, April 8.

NEW AUSTRALIAN ORCHIDS.

(Concluded from p. 472.)

Drahaea glyptoloma.—A slender plant, 6—9 inches high. Leaf thick, ovate cordate, about 5 lines in diameter. One-flowered. Lateral sepals and petals red-brown, about 4 lines long, recurved, linear; dorsal sepal rather longer, erect. Labellum dark red-brown, articulate at the end of the basal projection of the column, on a linear claw of about two lines. The central part of the labellum ovate convex, produced towards the end into an emarginate projection, and at the base into a glandular appendage resembling the head of the extinct *Armadio*- or *Glyptodon*. The recurved under-surface and basal part of the under-surface covered with branching hairs. Column about four lines, much curved, the wings forming two ovate auricles about the middle. Basal projections linear, about two lines. Stigma not produced into a long point (or rostellum?) as it is in *D. elastica*. Western Australia.

Thelymitra sonalis.—A slender plant, about a foot high. Leaf about 6 inches, linear, thick, rather deeply channelled. Bracts long and stems clasping. Flowers one or two. Sepals and petals ovate acute, about three lines. Petals yellow. Sepals yellow inside, dark red brown outside. Column three lines, not hooded, but produced above the anther, undulate or almost denticulate between the lateral appendages, which project horizontally forward and are broad and rugose. The wings of the column enclose it for more than half its length at its base and form a cup, with a central spur more or less developed in front of the stigma, giving the column an urn-like appearance. Anther obtuse, or slightly emarginate, protruding over the stigma, and continuing when mature to include the pollen masses. South Australia.

Thelymitra luteicolum.—A rather stout species, about 1 foot high. Leaf about 8 inches, broadly linear, deeply channelled in front, and slightly so on the sides. Bracts long, and stem clasping. Flowers three to five, bright pink. Sepals and petals ovate-acute, about 4 lines. Column about 2 lines, almost hooded, three-lobed between the lateral appendages. Lateral appendages having two lobed wings at the bases, and dense yellow cilia at the ends turned upwards. Anthers obtuse, protruding over the stigma. South Australia.

Thelymitra rubra.—A slender species, about 1 foot high. Leaf linear, half 5 inches. Bracts very narrow, stems clasping. Flowers one or two, bright red. Petals and sepals ovate-acute, about 5 lines. Column about 3 lines, produced above and behind the anther, but not hooded, slightly denticulate between the lateral appendages. Lateral appendages lanceolate, produced horizontally beyond the anther almost to a point, not ciliate, but covered on both sides densely with rugose glands. Anther obtuse, continuing to enclose the pollen masses behind the stigma, but produced over it. (This species is closely related to *T. carnea*, but the flowers are much larger and of a brighter colour. It opens constantly, is evidently not so absolutely self-fertilising, and is easily distinguished by the large and rugose lateral appendages of the column.) South Australia.

Thelymitra grandiflora.—A very robust species, from 1 foot 6 inches to 2 feet 6 inches high. Leaf lanceolate, about 9 inches long, and about to lines broad, thick, forming a closed loose sheath round the stem for 3 or 4 inches. Lower bracts sheathing in the same way far more than half their length. Flowers about thirty in a dense spike, greyish-blue. Petals and sepals oblong obtuse concave, about 8 lines. The back of the sepals much darker in colour. Column about 4 lines, hooded. The hood remarkably flat, broad, and smooth, of a leaden colour. The space between the extreme lateral appendages consisting of two large wings, deeply denticulate along the edges, and a much smaller arched central wing also denticulate. The extreme lateral appendages produced horizontally and terminating in white penicillate tufts. The wings of the column inflated and inclosing the lower part of the stigma in a cup. Anther not produced over the stigma and remaining behind it. (This is the largest and most beautiful *Thelymitra* known.) South Australia.

Thelymitra nuda.—A slender species, hardly 1 foot high. Leaf linear, about 6 inches, thick, and but slightly channelled. Flowers two or three, lilac-blue. Petals and sepals oblong lanceolate acute, about 3 lines. Column 2 lines, of a squarer form than in other species, hooded. The hood deeply and acutely emarginate, with entire edges, very dark, but covered with a hoary bloom resembling mould, which easily rubs off, leaving the dark under-colour apparent. Extreme lateral appendages produced horizontally, covered on the outside with abortive wings, and yellow cilia, smooth on the inside. Anther acute, not produced beyond the stigma and remaining behind it. (Found growing in standing water.) Western Australia.

Diuris lertii.—A slender species, from 8 inches to 1 foot 6 inches high. Leaves from 3 to 6 inches, numerous, linear, spirally twisted, enclosed at their base by a sheath. Flowers two to six, light yellow. Petals elliptical, stipitate, 7 or 8 lines, including the dark brown claw of about 2 or 3 lines. Lateral sepals about 7 or 8 lines, linear, green. Dorsal sepal almost triangular, embracing the column, about half the length of the other sepals. Labellum

three-lobed. The lateral lobes half the length of the central, falcate denticulate along the upper edges, striate with brown lines. Central lobe ovate-rhomboid, about six lines, including the linear portion between the wings, on which portion are two raised lines, perfectly smooth, as is the whole of the labellum. The rhomboidal portion is raised along the centre in a sharp ridge. Wings of the column of the same length as it, toothed. (This species is closely allied to *D. pedunculata*, but easily distinguished from it by the absence of all pubescence on the labellum, and by the spiral leaves.) Western Australia.

Prasophyllum attenuatum.—A very slender, wiry species, from 1 foot to 1 foot 6 inches high. Leaf 9 inches. Leaf-lamina 3 inches. Flowers about forty, not dense, on a spike of about 5 inches. Lateral sepals not two lines, greenish with white edges, oblong-ovulate at the ends, with blunt points. Dorsal sepal about two lines, oblong, hardly acuminate, slightly recurved. Petals not two lines, white with purple streak, oblong, blunt. Labellum about two lines, ovate-oblong, saccate at the end. Disc about two-thirds of the length of the labellum, hardly raised above it with five slight ridges towards the end. Appendages of the column falcate acuminate, unequally two-lobed. Lower lobe obtuse. Anther obtuse, shorter than the rostellum. Western Australia.

Prasophyllum plumbeiforme.—A slender species, about 1 foot to 1 foot 6 inches high. Leaf about 6 inches. Leaf-lamina hardly 2 inches. Flowers about forty in a long feathery spike. Sepals and petals oblong acuminate, about 2 lines. Lateral sepals white with green stripe. Dorsal sepal reddish edged with white. Petals white with purple stripe. Lateral sepals not united. Labellum not gibbous, oblong, tapering, slightly reflexed for about one-third of its length. Two parallel slightly raised plates on the disc. Lateral appendages of the column falcate acuminate, unequally two-lobed. Rostellum slender, longer than the appendages. Anther short, hardly acuminate. Western Australia.

Prasophyllum triangulare.—A rather robust species, 1 foot or more high, very dark coloured. Leaf about 10 inches. Leaf-lamina about 5 inches. Flowers dark red-brown, about thirty in a long spike. Lateral sepals united almost to their points, together [ovate, acuminate, glandular at the base and along the suture; dorsal sepal rather longer, about 3 lines. Petals lanceolate, shorter than the sepals. Labellum about 2 lines on a rather long claw, triangular, very slightly recurved. Edges entire, and slightly undulate, the disc forming a raised triangular plate, nearly as large as the labellum, somewhat swollen towards the points, and irregularly covered with small sessile calli. Appendages of the column broad at the base, falcate, acuminate, equal in length to the rostellum, thickened on the outer margin into three or more callosities. Anther much shorter than the rostellum, hardly acuminate. Western Australia. Robert Fitzgerald, Surveyor-General's Office, Sydney, Jan. 19.

JOTTINGS ROUND BRISTOL.

SPRINGFIELD, the seat of Francis W. Savage, Esq., in the parish of Westbury-on-Trym, can boast of a garden locally celebrated for conception of design, neatness, and a stock of choice flowers all the year round. When one hears a little on the way of the dainty stock the hot-houses contain one may be excused for a little impatience to reach the goal for which the journey was undertaken. And, as if to gratify the desire which had not been expressed, I am, after formal introduction, shown into the fernery where a goodly stock of the charming *Adiantum farleyense* is ready grown for furnishing—and such healthy fronds! How they shine under a ray of light, and seem too delicate even to touch, much less to expose them to the ordeal of what is best known as furnishing. But no difficulties are even hinted at at Springfield. There are plenty of houses and plenty of plants, and tender subjects are changed frequently, and the gardener, like a wise man, does not shed a tear because he has to cut the heads off his plants just as they are approaching full beauty. Upon the contrary, he will tell you what a grand display such and such a plant will make in a day or two when fully out, and I verily believe that by force of habit Mr. Edwards, the gardener, enjoys a glass or vase of cut flowers done up in style as much as an

exhibitor enjoys a specimen plant when he pronounces his last "There!" after several hours' training. Well, so much for habit. The Ferns, as I have said, are unique in size and finish for the purpose for which they are specially grown. *Nephrrolepis exaltata* is another favourite Fern for house-work. *Calanthes*, *Eucharis*, *Lancratium*, and such-like, are grown largely, and all sweet-scented flowers are grown in quantity. *Illicium sinensis variegatum* is grown as a stove creeper, and a charming ornament it makes. The Camellia-house is filled with established plants in flower, and contains the oldest *Maréchal Niel* Rose in the neighbourhood of Bristol. A fine display of *Pelargoniums* in flower is in an adjoining house, Guillon Mangell is highly spoken of among others, and there are also some grand specimens of *Imantophyllum* *miniatum splendens*, with numerous flower-spikes highly coloured. Many plants are also grown singly in small pots for house furnishing. A dark leaved *Begonia* named *Sambo* has a good effect in the plant stove, among choice *Crotons*, *Dracenas*, healthy *Orchids*, many of which are in flower, and a good plant of *Loya imperialis*. Forcing of fruits and flowers is conducted equally successfully in a range of low span-houses, and the vineries are showing well for Grapes in addition to being stocked with plants for supplying cut flowers. In an isolated or detached house, I observed a large stock of *Azaleas*, and rare specimens of the old favourite *Farfugium grande*. *Palms* and *Amaryllis* are well done in another structure, and indeed a system of well-matured management seems to prevail over the entire establishment. Nor are out-of-door plants or shrubs less cared for. Shrubs are conspicuous for health and arrangement; there is no such thing as a painful struggle for life among the commonest plants or the choicest specimens. Roses are neatly arranged, in good health, and legibly named, so that he who is not troubled with obliquity of vision, and is not well posted up in *Rose lore*, may read the name of every *Rose* with comfort from the walks. Here is a creeper, which is not too common covering a wall—*Aristolochia Sipho*, which succeeds well at Springfield; the flower is like Turkish tobacco-pipe, and the colour is chocolate. Through the kindness of Mr. Savage I had a peep at the show of cut flowers in the house. But first of all let me just mention the rich collection of oil paintings which adorn the walls, and the numerous other valuables from Japan and China, which are in the entrance hall and other rooms and which are elegant and costly representations of art in the respective countries from which they have been procured. The cut flowers are arranged upon a distinct and very effective principle. There is no mixing of half a dozen kinds of flowers in a glass. There is one of *Marguerites*, another of *Narciss*, a third of *Iris*, or a bunch of *Camellias*, *Pelargoniums*, or *Primulas*. *Orchids* are arranged upon the same principle, and a medium-sized glass filled with white *Arum* looked all the world over as if they had been growing there, so naturally are they arranged among their own leaves! The glasses with the different coloured flowers are then arranged so as to produce the desired harmony or contrast as the case may be, and the method though simple has the merit of showing off distinctly and in continuation the beauty of all kinds and colours of flowers.

HENLEAZE, the seat of S. Derham, Esq., lies north of Bristol, and enjoys a commanding view of the Welsh hills and many local places of note. At the entrance gate there is a remarkable specimen of the *Kilmarnock Weeping Willow*, over 20 feet high, with the branches drooping close to the stem. The spring garden is showing symptoms of active growth, and a little colour in the form of star bells, having the lines drawn with different coloured *Daisies*. Mr. Farmer, the gardener, is found busy among his Vines, pinching and training a fine old *Vine* grown upon the extension system, and which carried 210 bunches last year, and this year promises to be more fruitful than ever. The plant-stove adjoins this vinery, and the collection consists of the usual variety grown for private purposes. A second division is filled with Ferns, capital plants of free-growing kinds, such as *Lomarias*, *Blechnums*, and *Adiantums*, the latter, of course, for cutting, and the former for grouping in the house when extra decorations are required. There are two young vineries, in which the Vines are progressing rapidly, and in the second division of which the Grapes are already thinned and swelling away. The occupants of the Melon and Cucumber houses are both early and show well for good crops. A large

orchard-house is, however, the notable fruit structure of the place; it is 70 feet long, 45 feet wide, and 20 feet high or more. Vines are grown upon one side, Peaches and Nectarines upon the other, and fruit trees in pots in the centre of the house. The Vines and other fruit trees are very fine examples of cultural skill, and Roses trained up the ties supporting the house are equally if not more remarkable. The conservatory is gay with a miscellaneous stock of plants, in which good plants of *Convallaria polygonatum* figure conspicuously. Eupatoriums grown specimen fashion and a good show of bulbs are the chief features in the greenhouse. The fruit garden is noted for its collection of cordon Peas and other fruit trees, which yield a profitable supply of fruits in their different seasons, and are free from most diseases incident to hardy fruit trees. As a fruit garden there is even at this early date every prospect of abundant crops.

REDLAND LODGE is situated in the parish bearing the same name, about 2 miles from Bristol, and is owned by J. C. Wall, Esq. The mansion is approached by a beautiful Cedar avenue, and the grounds are tastefully laid out and kept in apple pie order. The garden is of average size, consisting of the usual departments, in which every branch of modern gardening is creditably represented. The hot-houses are of modern construction, and their inmates are, without exception, in first-rate condition. In the vineries good crops of Grapes are showing, and they are also very economically used for purposes of plant growing—not the common herd of bedding plants alone, but useful decorative subjects, such as bulbs (spring-flowering), Azaleas, zonal Pelargoniums, Richardias, *Primulas*, and other useful plants. Tomatos for an early supply are in an advanced state, and are of course fruited in pots. The back wall of one of the vineries is covered with *Tropaeolum Lobbianum*, which produces a never failing supply of flowers, and is struck fresh from cuttings every season. The Vine borders are covered with glass, sashes being fitted into a permanent framework, the former being movable, and when laid on having sufficient pitch to throw off rain as quickly as it falls. In the autumn about a foot in depth of dry leaves is laid on the surface of the border, then the sashes are fixed on for the winter, and the roots are as cosy as if they were in an inside border, and in a vastly more natural condition. The writer prophesied that hothed Grape-growing would die out in time—and it is so! The sub-soil in this case is unfavourable, and almost impervious to moisture. In a range of forcing-houses, Cucumbers, Strawberries and Grapes are remarkably well-grown, and in addition flowering Begonias are trained upon the walls by the paths, which has an exceedingly cheerful effect. Bouvarhas and Eucharis are quite gay with their ever attractive flowers—a whole shelf of the former is laden with plants in full flower, scarlet and white, which are in great request for cutting purposes here as elsewhere. At the end of the range a house of young Vines twelve months old is in splendid condition. In the plant-houses a miscellaneous collection of plants is well grown, and in a new range of Peach-houses the crop is a marvellous one, and climbing Roses of the Jules Margottin type are quite as well grown as the Peaches. Passing on to the more homely department, *i.e.*, the kitchen garden, the spring crops are progressing satisfactorily, and in the Mushroom-house there is such a sight of Mushrooms as would make an epicure smack his lips. Asparagus is forced by means of sanitary pipes being placed beneath the beds, trenches are taken out upon either side the beds, which are filled in with fermenting materials, the heat passing through the pipes underneath the bed. In the grounds two fine Oak trees are notable objects, and an iron screen clothed with Ivy and ornamented on the top by semicircular arches clothed with Roses and Clematis, is quite a novel feature, which strikes one at first sight. What must the effect be when the Roses and Clematis are entwined in bud and in leaf later in the year! Mr. Vallance is not an old gardener, but he is evidently old enough to cultivate plants and fruits in the first style of the day, and to keep a garden neat and orderly as well.

BERRY HOUSE stands on an elevated site, from which there is a delightful prospect, including magnificent views in the direction of the Severn and the Welsh mountains, and is the property of Mrs. Miller. The garden, with which

the writer is most interested, is of medium size, and like most gardens located not many miles from a large and thriving city, is well and orderly managed, fruit and plant growing being carried on with spirit if not enthusiasm. The conservatory so-called is rather in the shape of a curving corridor in which there is a display of spring flowers, among which *Salvia Ilicifolia*, perpetual flowering Carnations, Azaleas and *Camellias*, form the leading elements. The roof of the structure is covered with *Passiflora crerulea* and other creepers. The garden proper is enclosed by good brick walls, within which are the leading ranges of forcing and other houses. One of these consists of Cucumber, Melon, and pot Vine house, in which the crops are both early and abundant. The next range is in two divisions and in one of these an Allamanda trained upon the roof has made remarkable progress in little more than a year. Pines, Strawberries, and Orchids, are grown in these houses, the earliest variety of Strawberry here being *Brussels* of Prussia, which is fourteen days earlier than any other known variety, save and except *Black Prince*. The orchard-house is stocked with healthy fruiting Peach trees upon the walls, fruit trees in pots, and Strawberries upon shelves suspended from the roof. The plant stove is unequal span and is furnished with a marvellous supply of *Stephanotis* which covers the roof and which is flowering at every joint, and will continue to supply cut flowers for several months. The plants cultivated in pots are of the useful class, and are in beautiful order in their respective kinds. Flowering Begonias, *Franciscae*, *Centropegea Luceana*, *Euphorbia* and *Caladiums* are those that appear to have the greatest attention; health and cleanliness are, however, visible everywhere, and plants that are clean and healthy just now are sure to develop into something good before the end of the season. The Vines are in a fruitful state, and promise to bear crops as good as usual. The back walls are brightened up by planting Begonias against them, tall free growing sorts, such as *fragrans nitida* and *Fischeri*, and a variety very like the latter, but with rather more pink in it. The greenhouse is ornamented with a pretty arch of *Tropaeolum Lobbianum* which spans the path inside the door, and is one living mass of flowers drooping among a profusion of deep green leaves, which in the month of March is not to be despised. The collection in this house consists of the usual kinds generally cultivated in private gardens. Muscat Vines and the late fruiting black kinds are being brought forward quietly, and specimen Azaleas, Roses in pots, and other plants are sharing the same treatment. There is an old vinery of Hamburgs which still does good service as a late vinery—that is, late for Hamburgs. The stocks of hardy fruit obtained annually are generally equal to the demand, and upon the whole there is much pleasure and interest to be derived from a visit to this well managed garden, which is so successfully conducted by Mr. Gibson.

Apiary.

AN EARLY SWARM OF BEES.—After promising to come out for a fortnight my strongest stock of bees threw out a fine swarm on April 7 (Good Friday), and as I learn from many knowing people that one so early in the year is something remarkable, I am induced to make a note of it. It was rather annoying, too, that the insects should have elected to turn out just as we had sat down to dinner, for a comfortable meal under the circumstances was out of the question, and ere the swarm was quietly settled the edibles were about as cold as are "hot" cross buns. Probably rendered a little contrary by the prevalent east wind the queen must needs settle amidst a Peach tree on the wall, and here the swarm was as difficult to house as well could be. By dint of using dexterously the wing of a goose the queen and two-thirds of the insects were hived, and the rest found out their new home after a short time. My neighbour, who is a cool hand at his living, found his match for once, however, and having scorned a veil for his face got more than a dozen stings about the vital organs, but they seemed to affect him about as much as if his skin had been Junibo's hide. If the old proverb as to the relative values of a swarm of bees in May and of a load of hay is to be taken as authoritative, it would seem that a swarm in April is not only unusual, but almost, like the peck of March dust, should be worth a king's ransom. *A. D.*

Orchid Notes and gleanings.

PONTHIEVA MACULATA.—An exceedingly pretty and interesting Orchid (*Ponthieva maculata*) is now in flower at Kew, I believe, for the first time in cultivation. It is interesting alike for its structure and somewhat peculiar coloration. It is a terrestrial Orchid, with distichously arranged lanceolate light green leaves, 3–6 inches long, covered on both sides with long soft hairs (most of which are minutely gland-tipped), as are also the stem, bracts, ovaries, and outside of the sepals. The flowers are about 1 inch across their greatest diameter, and are arranged in an elongating raceme; the long green ovary is not twisted, so that the labellum points upwards, the petals occupying the position usually taken by the labellum, and, indeed, might easily be mistaken for it, as that organ is exceedingly small, being scarcely more than an oblong excavated nectar cup, about one-tenth of an inch long. The lanceolate odd sepal, which is directed downwards, is light buff-brown, becoming whitish at the acuminate tip, and tinged with green on the nerves. The ovate acute lateral sepals, in which perhaps the chief charm of the flower is centred, stand erect; they are white, tinged at the base with light brownish and beautifully marked with dark green spots, from the centre of each of which arises a perfectly transparent, glossy, adpressed, clavate hair (or gland?), which can scarcely be perceived except under a lens so transparent is it. The clawed, semi-ovate petals are pendent from the apex of the column, their straight edges being applied to each other, or even overlapping; they are bright buff, with three green nerves on the basal half of each. Altogether the flowers are very odd and exceedingly pleasing. The plant is a native of Venezuela. It was exhibited at the *soirée* given by Sir John Lubbock to the members of the Linnean Society, at Burlington House, on March 28th, and a drawing of it has been prepared for the *Botanical Magazine*. *N. E. Brown.*

ORCHIDS AT THE YORK NURSERY.—Like many others of our great nurserymen the Messrs. Backhouse & Son, York, are very considerably extending their collections of Orchids. The large span-roofed house, which was partly a vinery and partly an Orchid-house, is now entirely devoted to Orchids, and it is well filled with recently imported Cattleyas, *Dendrobiums*, and others. There were at the time of my visit—the first week in April—some very fine varieties of *Cattleya Mendelii* in flower. The plants had made very stout well-ripened bulbs, and they were much more exposed to the sun than I had previously seen Cattleyas. The leaves felt quite warm to the hand when the sun was shining on them. The large plants of *Cattleya Skinneri* from the Burton Constable collection, previously alluded to in the *Gardener's Chronicle*, had made very strong sheaths, and were bursting into flower. *Lelia flava*, introduced to this country forty years ago, but seldom seen in flower, had a fine truss of its golden-yellow flowers. It is a very distinct species, allied to *L. cinabarina*, the pseudobulbs being stouter and shorter. *Mamillaria Harrisonii* in flower is a beautiful Orchid, the sepals and petals creamy-white, labellum hairy, purplish-brown, marked with dark brown lines.

DENDROBIUM DENSIFLORUM.—In the gardens at Warnham Court, Horsham, the residence of C. J. Lucas, Esq. (gr. Mr. J. Duncan), there is a specimen of *Dendrobium densiflorum* with sixty fine spikes, most of them having three dozen flowers on a spike. I have seen many, but none with so many spikes as the above. *A. O.*

CYMBIDIUM EUBURNEUM.—On the opposite page we give an illustration of the remarkably fine specimen of *Cymbidium eburneum* exhibited by Mr. Mill, gr. to Lord Rendlesham, at the meeting of the Floral Committee held on March 14. It was a model of high cultivation, being in perfect health, and bearing twenty-nine of its beautiful ivory-white flowers, which, standing well up amid the bold recurved foliage, gave it a most distinct and noble appearance. We should be glad to know from Mr. Mill the mode of cultivation which produced so good a result.

Fig. 78.—*CYNODON ERUENENSIS*: FLOWERS PINK-YELLOW; LEAVES REDDISH. (SEE P. 496.)

Florists' Flowers.

DOUBLE AURICULAS.—It will no doubt be generally admitted that the single Auriculas are preferable to the double kinds on account of the possession of a more simple and better defined beauty, while the efforts the florist has put forth, and is still putting forth, to improve the Auricula are all in the direction of improving the single forms. The Continental florists, appearing to care but little for our fine forms of the show Auricula, have been slowly but surely selecting and improving double forms, though these are by no means numerous. For some time past we have been familiar with the double yellow and the double dark Auriculas, and it would be interesting to know how these originated, or from whence they were derived. The double yellow appears to be the oldest and most generally grown of the two; the double dark is scarcely so robust, and not so common. The double white, that used to be grown in Scotland and elsewhere to some extent, is now but little known, and consequently very scarce. The dark form are the most double; the yellow and white types are but semi-double forms, yet very interesting to many. The Continental florists appear to have been successful in raising some very full and fine double varieties, of which *Purpurea*, which was Cerebited by the Royal Horticultural Society last year, is the best known representative. It would appear that the Continental florists have proceeded along much the same lines with their double Auriculas as our English florists have with their double forms of *Primula sinensis*; they took care of any alpine Auriculas showing a tendency to produce superfluous petals from the centre of the flowers, and, seeding from these, gradually evolved the double form from them. It required much careful selection to get the fine types that are occasionally met with, but they are worthy of the time and trouble expended over the work. They grow less vigorously, and increase much less rapidly, than do the single varieties, and those who possess them have to wait patiently for accumulations of stock. They make charming subjects for pot culture, but to have fine flowers must not be over-potted. Fortunately there are so many lovers of flowers with different tastes that what one condemns as unsightly another may regard as specially attractive; and Nature, out of its great resources, provides for all, through the agency of the worker—man.

THE GLADIOLUS.—It is now quite time that the very latest bulbs should be planted. We have frequently planted them after the middle of April, and as late as the first day in May, but when they are planted so late as that they do not succeed so well as those planted earlier, and it cannot be supposed that the bulbs will ripen well. The ground has been in very good condition this year, and there cannot be any excuse on the score of unfavourable weather. I have always found them do best when the ground has been well worked during the winter, turning it over frequently in fine weather. We also reserve some fine maiden loam to put over the bulbs when they are placed in the drills, a little fine sand being scattered over them in the first place. The earliest planted bulbs will now be pushing through the ground; should there be any prospect of frost it is a safe plan to invert a pot over those that are through the ground, taking it off in the morning. We also sow our Gladiolus seeds the second week in April. A hot-bed is prepared for them about ten days previous to the time of sowing, as it takes about that time for the violent heat to subside. About 6 inches of Cocoa-nut fibre must be put over the manure in which the pots containing the seeds are to be plunged. Pots 6 and 7 inches in diameter are the best; each pot will contain about fifty plants. Those who grow very large quantities of seedlings are obliged to sow the seeds in the open border. If no hotbed was available it would be necessary to sow them on a warm border, but when the means are at command the methods I have described are the best, as the small bulbs produced during the ensuing summer and autumn will produce good spikes next year. *J. Douglas.*

THE DAHLIA.—The exhibition of Dahlias to be held at the Crystal Palace, Sydenham, in September

next, will no doubt give an impetus to the culture of this showy autumn flower such as it has not received for very many years. When Dahlia shows have been held in or near London in recent years they have not been well supported, nor could any reasonable person expect that they would be, as the prizes usually offered have been totally inadequate to the importance of the flower, and could not repay the exhibitors for the expense they are obliged to incur. On this occasion a few ardent cultivators have taken the matter in hand; they have either collected or subscribed sufficient funds, and with the aid of the Crystal Palace Company they have prepared a very liberal schedule, which will soon be issued; and the committee feel confident that a grand display of Dahlias will be forthcoming.

Such an exhibition as was wont to be held at the Crystal Palace when it was first opened, and those of us who can remember the exhibition held just a quarter of a century ago—when Mr. Charles Turner, of Slough, gained the 1st prize for fifty distinct Dahlias, Mr. John Keynes, his great rival, being 2d—will look forward with great delight to this exhibition. We are not likely to have such a display of Hollyhocks as was made on that occasion by Messrs. A. Paul & Sons, of Cheshunt, and Mr. Chater, of Salford Walden, but we shall have a greater variety in the Dahlia, and besides the variety there will be a great improvement in the form of the flowers, especially in what is termed the fancy section. Besides the show and fancy Dahlias, which will form the principal feature of the exhibition, the single varieties will be provided for in the schedule. These and the small-flowered or pompon section will be exhibited in bunches. The leading Dahlias, too, will be there; and as a bedding Dahlia is of no use unless it is dwarf and free-flowering, these will be exhibited in pots, to show the habit and the effect of the plants as they will appear in the garden. Dahlia growers are now preparing their plants; by this time they should be rooted, and ready for potting into 5-inch pots; and as soon as the state of the weather admits of it, they should be put out into cold frames. In that position they form fine healthy short-jointed plants, as the lights can be removed whenever the weather is favourable, and they can be placed over the plants if there is danger of frost; and as a further precaution mats may be thrown over the glass. The experienced grower needs not to be told to prepare his ground—that would be done in October—by trenching it deeply, working in plenty of manure at the same time. The soil should also be lightly forked over at intervals up to the time of planting. No amount of attention in the summer can make up for neglect in preparing the ground during the winter. *J. Douglas, Lovford.*

DOUBLE CINERARIAS.—The fine varieties which have been shown of late by Mr. R. H. Vertegans of Birmingham, and others, and particularly by Messrs. H. Cannell & Sons, at the meeting of the Royal Horticultural Society on Tuesday last, now show so much actual gain in the matters of size, fullness and colour, that one is inclined to exclaim, "Hold! enough!" The imminent danger appears to be of increasing the size of the blooms beyond a certain point when they must, we fear, become little better than monstrosities. The larger the size the less of floral beauty and a relative symmetry will invite attention. The varieties from Mr. Cannell appeared nearly perfect, and to improve them in size will seem something like spoiling them. The sorts were Phoebe, heavily edged with bright pale magenta on a white ground; Kate, with a narrow edging of pale pinkish magenta; Sophia, rich deep bright magenta, very fine and showy; Mary, rose-purple; Mr. T. Lloyd, bright bluish-purple, large and full; and Ada, deep indigo-blue. The variety named Sophia appeared to be a model double Cineraria. It is quite large enough for all purposes, and the flowers are as full as they can well be. We do not want double Cinerarias as large as Pyrebrams, and in regard to the single varieties, also, it is difficult to obtain a largely increased size without loss of form, symmetry, and beauty.

FLOWER POTS.—During the month of March 245,580 pots of all sizes, ranging from $\frac{1}{2}$ inch to 30 inches in diameter, were sent out from the Royal Factory, Weston-super-Mare, this being the largest number turned out in one month since Mr. John Matthews has had the works, now over eleven years.

The Kitchen Garden.

SEED SOWING, &c.—This will be a good time to sow the main crop of Broccoli and Kales, which should be sown in beds 4 feet wide, with an alley a foot wide between each bed. The ground should be trodden over and raked before the beds are marked out; these should be made square with the wall or walk, the seed should be covered with a quarter of an inch of soil from the alleys, which should then be raked, and the surface of the beds patted with the back of the spade so as to compress the soil and seed, and the alleys neatly cut off. After this the attacks of chafinches and sparrows must be guarded against, as recommended in our last Calendar. The following sterling varieties may be depended upon, and I will divide them into four classes; and in the order in which the respective kinds come into use, viz.:—Autumn varieties: Veitch's Self-Protecting, Grange's Early White Cape, and Early Purple Cape. Early winter varieties: Snow's Winter White, Backhouse's Winter White, and Early Penzance White. Early spring kinds: Brimstone, Chappell's Cream, and Frogmore Protecting. Late spring varieties: Cooling's Matchless, Carter's Champion, Cartlett's Eclipse, and Richmond Late White.

Advantage must now be taken of genial showers to plant out good breadths of Cauliflower, Cabbage, and Lettuce plants, also Brussels Sprouts, which should be planted in rows not less than 3 feet apart, and the same distance from plant to plant in the rows. Another sowing of Turnips and Lettuce should now be made, also a sowing of Salsify and Scorzonera (where used) should be made in drills an inch or so deep and a foot apart. Where Caroons are in request the seed should be sown at once in a box or pan and placed in a frame, and as soon as the seedlings have come through the soil they should be gradually hardened off and subsequently planted in trenches 1 foot deep and 16 inches wide and 4 feet from centre to centre, and about 16 inches from plant to plant in the row. The trenches are prepared similarly to those for Celery.

SCARLET RUNNER BEANS.—As our mode of growing these is somewhat different from that generally practised, and the results are thoroughly satisfactory, I will briefly state it. We grow two rows, each about 60 yards long and 8 feet asunder, which run east and west. We plant our first on or about April 24, in drills about 3 inches deep, and the second row about two months later, and in front (south) of the first row. And instead of using sticks 8 or 9 feet long as supports for the vines we use Ash poles as long as we can get them without being too thick and heavy—say from 20 to 30 feet long—which are stuck firmly in the ground, 1 foot apart, on either side the row of runners, and braced together by a series of bean-sticks fastened longitudinally on either side the upright sticks at 6 or 7 feet from the ground by means of a series of cross-ties made of tarred string, by which means the rows of sticks are made secure against the effects of rough winds. Instead of stopping the runners, as is usually done, we allow them to grow uninterrupted, and so cover their allotted space, thereby prolonging considerably the supply of runners. We frequently gather, by the aid of a long pair of steps, from the row sown the end of June, which is protected by the shelter afforded by the first row from the effects of cutting winds and autumn frosts, good supplies of runners to the middle and end of November.

GARDEN WORK.—This will consist in the earthing-up of Cauliflowers, Cabbage plants, and rows of Peas, and Broad Beans, together with the sticking of the former and the stopping of the haulms of those now coming into flower, which, owing to the temporary check which the plants thus receive, cause them to pod quicker than they would do under ordinary treatment. All Peas and Beans which have been staked and earthed-up, should now have a good mulching of well-rotted dung put on either side the rows which will not only conserve the moisture at the roots, but maintain the latter in a more equable condition. This done, it will be advisable, in light soils, to give both

Peas and Beans a good watering at the roots. Prick out in nursery-beds young plants of Cauliflower, Cabbage, Brussels Sprouts, Savoys, Leeks, and Lettuce, resulting from the first sowing out-of-doors, in a warm border, the Lettuce 3 inches apart every way, and the other sorts 6 inches; and water them through a rose if the condition of the weather render its application necessary. Thin out successional sowings of Turnips and spring-sown Spinach to a few inches from plant to plant in the rows, and subsequently thin them out to 9 inches. Vigorous use must now be made of the Dutch hoe, not only with a view to stimulating growth in the rising crops, but the cutting down of weeds wherever they appear—an operation for which the beautiful weather which we have been having has been highly favourable. Potatoes just pushing through the soil should have a little of the latter drawn up to them, and a slight protection afforded them when there is likely to be frost. Failing a reader, though not a more efficient means of protection, a flower-pot may be put over each haulm (where the plantings are not large) at night, and removed in the morning.

MUSHROOMS.—Beds made and spawned in January and February, providing that the spawn was good, and had been inserted under the surface of the beds when the heat had declined to 75° or 70°, and that they were subsequently eased over with finely-sifted adhesive loam beaten firmly together with the spade, will now be yielding good supplies of Mushrooms. These beds, from the time of moulding them—the soil being damp at the time—have not required any after-attention in the way of watering, inasmuch as the temperature of the house ranged from 50° to 60° without the aid of fire-heat, a circumstance which rendered the application of water in any way unnecessary. It will be advisable in modern air-tight-built houses to leave the roof-ventilator a little open in order to prevent a stagnant atmosphere, which would be neither congenial nor beneficial to the production of Mushrooms. The next bed, or series of beds, should be made out-of-doors under a north wall, and for which purpose collect horse-droppings and spread them in thin layers in a dry shed, after which, when the necessary quantity has been collected and turned over a few times, form into beds, spawn, and ease over with soil in the ordinary way, and then cover with loam litter from the stable-yard: these beds will yield supplies of Mushrooms in July and August. *H. W. Ward, Longford Castle, Wills.*

NOTES ON VEGETABLES.

A SEEDLING RHUBARB.—I send for your inspection a sample of a seedling Rhubarb of mine; it is remarkably early (we have been pulling for weeks in the open ground), very prolific, never produces a seed crown, and is of a beautiful colour. *Charles Kersting, Stead Syke Nurseries, Brighthelm.* [The stalks averaged 15 inches in length and 3½ inches in diameter, beautifully coloured, as our correspondent states, and of a pleasant mild flavour when cooked. Ed.]

Peaches and Nectarines.

WE are having a good spell of splendid weather for forcing, and very little fire-heat has been required in Peach-houses during the daytime; in fact it is better turned off altogether when the temperature rises to 65° on warm, bright sunny days, to prevent the temperature getting too high, which in very light houses it is apt to do if much artificial heat is used. The chief work in early and second houses will be tying-in the young shoots, which keep as straight as possible; stopping close any shoots at the base of which there are fruit, pinching out laterals and the points of any gross shoots. This treatment applies to old-established trees. Where the trees are young and it is desirable to get the wall or trellis covered as quickly as possible the side laterals may be laid-in, and if well ripened they will produce a good quantity of strong healthy bloom for fruiting next season. Examine borders, and if at all approaching dryness, give a thorough soaking of tepid weak manure-water. Keep a steady night temperature of 65°, allowing it to fall to 60° by morning.

Succession-houses will require "final" disbudding, thinning fruit, and heeling down. Attend well to directions already given as regards syringing trees, damping and watering borders, &c.

Trees in late houses will have set their fruit by this time, and may have a gentle syringing with tepid water twice daily, but it should be done very early in the afternoon to allow them to get thoroughly dry before night. Ventilators must also be closed on cold, frosty nights; but, unless we have more frost than we have had for the past fortnight, no fire-heat need be used. Disbudding will require daily attention. We have only a few trees here on the outside walls, and they are blooming tolerably well. *J. Wallis, Keele Gardens, April 11.*

Plants and their Culture.

STOVES.—The inmates of these houses will now, where under good cultivation, be making a vigorous growth, favoured to a great extent by the congenial weather for many weeks past. The night temperature may range now at about 70°, when the fires are banked up for the night. If found at 65° in the morning do not excite the fires to a great extent when there are indications of a bright sunny day, but rather keep them somewhat steady. Great watchfulness in this respect is necessitated, although it is a point that is often overlooked or ignored as not being worth close attention. Hot pipes and bright sunshine mean an extra and excessive amount of air, thereby causing too rapid evaporation. This is very detrimental to many tropical plants that delight in a moist atmosphere; it also gives encouragement to red-spider and thrips, and is the forerunner of many other evils. If perchance there should be a break of bright sunshine after a cold or windy and perhaps cloudy morning we find it a good plan to run down the blinds if the pipes are hotter than is desirable. This will counteract a too rapid rise of the thermometer, and obviate the giving an undue amount of air. With the increased temperatures now attained a more liberal use of the syringe will be necessary. We shall now make it a practice to use this indispensable article before leaving off time, as well as mornings and at closing in the afternoon. This will more especially apply to such plants as Crotoms, some of the Palms, and any other plants where red-spider is likely to gain a temporary standing. The evaporating troughs must now be kept filled, in which a little guano-water may also be occasionally poured with advantage. Any plants of *Eucharis amazonica* that have given a good supply of flower during the winter should be induced to make a free growth, another good return may then be expected in the summer. Pot any that are become root-bound before the plant shows signs of exhaustion. Give them a good lasting soil of a sound fibrous nature, in the which they can receive abundance of water without danger of becoming sodden. Gesneras should now be shaken out of the old soil and started into fresh growth, such as those that belong to the tuberous-rooted section. Cuttings may be easily struck of *G. Donckelaarii*, and will be found useful in the autumn. Some cuttings should also be struck of *Euphorbia jacquiniiflora*. Plants of *Poinsettia* that are wanted of extra size and vigour may also be sent to and started into fresh growth. An early batch of these plants will be valuable to succeed the *Chrysanthemums* in the autumn. Endeavour to keep the stock of *Thysanacanthus rutifolius* in good health; old plants of this showy subject well repay the extra trouble bestowed on them. These remarks also apply to *Centropogon Lucyanus*, cuttings of which will also make excellent flowering stuff another winter if got in without delay.

WARM GREENHOUSE.—Keep the stock of *Fuchsias* in active growth, potting those on into larger pots that it is desired to increase in size more rapidly. Pinch the young shoots after having made two pairs of leaves, leaving the leader only, if pyramids are required; cease stopping about six weeks before they are wanted in flower, and then feed liberally with manure water. Solanums that have made good growth since they were cut back may be gradually hardened off into a cold pit or frame, where they will be less liable to insects. Coleus of the fancy kinds struck from cuttings this spring should have liberal treatment; they will, however, make more robust and sturdy growth, if not grown in too much heat. If intended later on for the conservatory, see that the pots are well filled with roots previously, in order the better to withstand rough treatment. Some plants of

Plumbago capensis grown on now will be useful for the same purpose. Plants of *Spiranthes* that have ceased flowering may be spurred back if becoming too encroaching in size. These plants are best as standards in my opinion. Indian *Azaleas* that have flowered and which are starting into fresh growth should be potted, if this operation is necessary; a good long season will then be before them in the which to lay hold on the new soil, which should consist of the best of peat only, if durable plants are desired. *Camellias* also will now be making their season's growth, this will be greatly aided by a moist atmosphere. Potting of these had better be deferred till the young shoots are somewhat hardened, but should be seen to before the buds are set. *Abutilon Sellowianum marmoratum* should have attention paid it, being a most useful decorative plant. The next season's stock of *Bouvardias* and tree *Carnations* must be seen to; do not let any remain too long in their cutting pots. A late batch of pot roses placed in a genial atmosphere will come in serviceable before those from outside are to be had in any quantity. *James Hudson, Gumerbury House, April 11.*

SALVIA GESNERIFLORA IN SMALL POTS.—Plants of this *Salvia*, with from six to eight flower-spikes growing in a 48-sized pot, make very pretty ornaments for a sitting-room during the spring months. A number of plants of many varieties of *Salvia* are so common that well-grown small plants are seldom seen, if indeed many people attempt to grow them. That, however, they can be grown into handsome objects there can be no doubt. A gardener in a leading establishment in Devonshire grows a whole batch of them for furnishing purposes, and the dwarfness of the plants, and their healthy foliage, as well as the freedom with which their flowers are produced, should at least attract the attention of cultivators who require quantities of easily-grown plants for various decorative purposes. The point in their cultivation that must be especially attended to is to nourish the plants well, so as to retain abundant foliage, as under a restricted system of cultivation, flowers are freely produced. *H. H.*

Notices of Books.

Our Homes, and how to Make them Healthy.

Messrs. Cassell & Co. are publishing in monthly parts what promises to be a very useful treatise on the construction and arrangement of dwelling-houses in all their details. Some knowledge of the requirements of a house as regards health and comfort is obviously desirable for every one who has to live in one; but unfortunately, in most cases, the home-dweller is almost entirely at the mercy of the builder, to whom smallest of outlay—we will not call it economy—is the guiding consideration. Most people cannot build their own houses, and on the principle of subdivision of labour it is better they should have this to those whose special business it is to build. Unfortunately, however, the builder requires to be overlooked, and one of the most urgent demands of the day in and near our towns is some system of independent inspection, whereby proposing tenants and indwellers might be reasonably assured that the essentials of health and comfort were duly complied with by the builder. No dwelling-house should be allowed to be occupied previous to the inspection and certificate of an independent and competent surveyor. In the meantime publications like this of Messrs. Cassell may do much good.

A Practical Treatise on Tree Culture in South Australia. By J. E. Brown, F.L.S.

This is a useful little book, pointing out the desirability of planting trees in South Australia, with a view of improving the climate, of increasing the quantity and quality of her agricultural products, and of promoting prosperity in every department of her industries. Sound practical directions are given as to the preparation of the soil, the number of trees to be planted per acre, and their distances apart, the special measures to be adopted in particular situations—such as the sea-coast, parks, and streets; the best forms of tree-grains, the most appropriate methods of pruning and thinning, the formation of hedges, and the like matters, applicable in any country. Besides this, the cultivation of *Wattles* (*Acacias*) is advocated for the sake of their bark used for tanning, and an explanation given of the method of treating of plants in Bamboo tubes or joints of *Arno do* donax plunged in the ground, and in which the seeds are sown. After a year or two the seed beds are removed, leaving the roots of the young plants at liberty. A descriptive list of trees suitable for planting in South Australia is given, and, at the end, a monthly calendar of operations. The book is eminently practical, and much of it is applicable anywhere.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY	April 17	Sale of Imported Orchids, at Stevens' Rooms.
		Sale of Established Orchids, &c., at the Mary, by Protheroe & Morris.
TUESDAY	April 18	Sale of specimens, Plants, of the Koppell Park Nursery, Norwood Road, by Protheroe & Morris.
		Flower Show in Town Hall, Birmingham (two days).
WEDNESDAY	April 19	Sale of Established Orchids, at Stevens' Rooms (two days).
		Royal Horticultural Society of Ireland's Spring Show.
THURSDAY	April 20	Linnæan Society meets at 8 P.M.
FRIDAY	April 21	Sale of <i>Lilium auratum</i> Bulbs, at Stevens' Rooms.

IT is quite evident that we have not yet got to the bottom of the question, TO PRUNE OR NOT TO PRUNE? There is a great deal to be said upon both sides, and when that is so each case must be judged upon its own individual merits, and no attempt made to draw a hard and fast line. What will suit in one locality or under one set of conditions will not do so in another. What is appropriate treatment for one variety is not so for another. Hence the great value of basing our experience on extended experiment, and not on observation merely. We have been led to make these rather trite remarks from having lately witnessed an interesting experiment now in progress at Gunnersbury under the care of Mr. HUDSON. Mr. HUDSON had reason to be dissatisfied with the unproductiveness of some standard Pears of Josephine de Malines and of Williams' Bon Chrétien. These had been pruned and cut back in the usual manner, but their yield was not in proportion, indeed they were almost barren.

Thinking that this recurrent though partial removal of lungs and kitchen—for that is what it amounts to—might afford a reason for this unproductiveness, the experiment has been made, as has indeed often been done before, and is all but universal in market gardens, of letting them alone, for a time at least. A tree of Josephine de Malines, previously nearly sterile, was suffered to grow at its own sweet will for the last two years, and is now full of bloom—the flowers produced, not on thick scabby fruit-spurs, but on the ends and along the sides of long slender whip-like shoots as flexile as withies, characteristic of this variety. The Bon Chrétien is in like case, but its habit, as our fruit-growing readers well know, is different. Another tree of Josephine de Malines close by, which has only been left alone for one year, has scarcely a bloom upon it. Whether it will clothe itself with a livery of white next season depends on the season, and remains, of course, to be seen, but the experience of its fellow gives good ground for expectation that it will do so if the conditions are otherwise favourable. Again, it by no means follows because in a certain variety known to produce its flowers in a certain way the let-alone policy succeeds for a time that it is best for all other varieties, or even for that particular variety, for a continuance. It would be so, no doubt, if we wanted timber; but we do not ask for timber from a fruit tree. It must not, however, be overlooked, that in the artificial cultivation of fruit, as we understand the term, in gardens, the conditions of growth must be to a large extent, and up to a certain period, the same as those regulating the growth of leaves and wood. The fruit of the Grape, of the Apple, of the Pear, or what not, in its natural state is a very different affair from what our ancestors and ourselves have made it. It follows that the conditions, such as gradual arrest to growth, by heat, by drought, or in what manner so ever produced, which are more or less essential to the production of fruits and seeds in the natural state, are not necessarily the same, at any rate in degree, as those which are concerned in the production of garden fruits.

The fruit of the Pear and of the Apple is the core; the fleshy covering to the core which

we call fruit is not really so. Hence it will readily be understood that the direction and amount of growth required to produce a thick fleshy flower-stalk with its savory principles stored up in it may be very different from those demanded by the relatively small wild fruit and from those required for the most perfect elaboration of the true fruit and seed. We do not as a general rule grow Cucumbers or Grapes or Pines for their seeds. The most perfect cultivation of either of these would be—*is*, that which ensures the continuous and rapid growth and development of the pulpy investment of the seed, which is a different matter altogether from the development of the best seed. Quick, continuous growth, high feeding proportionate to digestive powers, fresh air and plenty of it, if at the right temperature, these are among the things to be aimed at, varying, of course, according to circumstances. But when fruit has to be "set," and when the ripening process begins, and especially when seed has to be ripened—when within its tissues food has to be stored up for the young plant within—when colour, flavour, aroma have to be got into the fruit, or what we call fruit—then our treatment at once becomes different. We cut off supplies to some extent, we raise the temperature, we turn all attention to the consolidation and maturation of what we have got rather than to the obtaining of more. Even light, if we consider it as apart from temperature, is now not so essential as it was.
